# Package ‘AzureStor’

March 16, 2021

**Title**  Storage Management in 'Azure'

**Version**  3.4.1

**Description**  Manage storage in Microsoft's 'Azure' cloud: [https://azure.microsoft.com/services/storage/](https://azure.microsoft.com/services/storage/). On the admin side, 'AzureStor' includes features to create, modify and delete storage accounts. On the client side, it includes an interface to blob storage, file storage, and 'Azure Data Lake Storage Gen2': upload and download files and blobs; list containers and files/blobs; create containers; and so on. Authenticated access to storage is supported, via either a shared access key or a shared access signature (SAS). Part of the 'AzureR' family of packages.

**License**  MIT + file LICENSE

**URL**  [https://github.com/Azure/AzureStor](https://github.com/Azure/AzureStor) [https://github.com/Azure/AzureR](https://github.com/Azure/AzureR)

**BugReports**  [https://github.com/Azure/AzureStor/issues](https://github.com/Azure/AzureStor/issues)

**VignetteBuilder**  knitr

**Depends**  R (>= 3.3),

**Imports**  utils, R6, httr (>= 1.4.0), mime, openssl, xml2, AzureRMR (>= 2.3.0)

**Suggests**  AzureAuth, readr, knitr, rmarkdown, jsonlite, testthat, processx, uuid

**RoxygenNote**  7.1.1

**NeedsCompilation**  no

**Author**  Hong Ooi [aut, cre], Microsoft [cph]

**Maintainer**  Hong Ooi  

**Repository**  CRAN

**Date/Publication**  2021-03-16 08:40:06 UTC

acquire_lease Operations on blob leases

Description

Manage leases for blobs and blob containers.

Usage

acquire_lease(container, blob = "", duration = 60, lease = NULL)

break_lease(container, blob = "", period = NULL)

release_lease(container, blob = "", lease)

renew_lease(container, blob = "", lease)

change_lease(container, blob = "", lease, new_lease)
Arguments

container A blob container object.
blob The name of an individual blob. If not supplied, the lease applies to the entire container.
duration For acquire lease, the duration of the requested lease. For an indefinite duration, set this to -1.
lease For acquire lease an optional proposed name of the lease; for release lease, renew lease and change lease, the name of the existing lease.
period For break lease, the period for which to break the lease.
new_lease For change lease, the proposed name of the lease.

Details

Leasing is a way to prevent a blob or container from being accidentally deleted. The duration of a lease can range from 15 to 60 seconds, or be indefinite.

Value

For acquire lease and change lease, a string containing the lease ID.

---

adls_filesystem Operations on an Azure Data Lake Storage Gen2 endpoint

Description

Get, list, create, or delete ADLSgen2 filesystems.

Usage

adls_filesystem(endpoint, ...)

## S3 method for class 'character'
adls_filesystem(endpoint, key = NULL, token = NULL,
     sas = NULL, api_version = getOption("azure_storage_api_version"), ...)

## S3 method for class 'adls_endpoint'
adls_filesystem(endpoint, name, ...)

## S3 method for class 'adls_filesystem'
print(x, ...)
list_adls_filesystems(endpoint, ...)

## S3 method for class 'character'
list_adls_filesystems(endpoint, key = NULL,
                      token = NULL, sas = NULL,
                      api_version = getOption("azure_adls_api_version"), ...)

## S3 method for class 'adls_endpoint'
list_adls_filesystems(endpoint, ...)

create_adls_filesystem(endpoint, ...)

## S3 method for class 'character'
create_adls_filesystem(endpoint, key = NULL,
                        token = NULL, sas = NULL,
                        api_version = getOption("azure_adls_api_version"), ...)

## S3 method for class 'adls_filesystem'
create_adls_filesystem(endpoint, ...)

## S3 method for class 'adls_endpoint'
create_adls_filesystem(endpoint, name, ...)

delete_adls_filesystem(endpoint, ...)

## S3 method for class 'character'
delete_adls_filesystem(endpoint, key = NULL,
                        token = NULL, sas = NULL,
                        api_version = getOption("azure_adls_api_version"), ...)

## S3 method for class 'adls_filesystem'
delete_adls_filesystem(endpoint, ...)

## S3 method for class 'adls_endpoint'
delete_adls_filesystem(endpoint, name, confirm = TRUE, ...)

Arguments

- **endpoint**  Either an ADLSgen2 endpoint object as created by `storage_endpoint` or `adls_endpoint`, or a character string giving the URL of the endpoint.
- **...**  Further arguments passed to lower-level functions.
- **key, token, sas**  If an endpoint object is not supplied, authentication credentials: either an access key, an Azure Active Directory (AAD) token, or a SAS, in that order of priority. Currently the sas argument is unused.
- **api_version**  If an endpoint object is not supplied, the storage API version to use when interacting with the host. Currently defaults to "2019-07-07".
- **name**  The name of the filesystem to get, create, or delete.
For the print method, a filesystem object.

For deleting a filesystem, whether to ask for confirmation.

Details

You can call these functions in a couple of ways: by passing the full URL of the filesystem, or by passing the endpoint object and the name of the filesystem as a string.

If authenticating via AAD, you can supply the token either as a string, or as an object of class AzureToken, created via AzureRMR::get_azure_token. The latter is the recommended way of doing it, as it allows for automatic refreshing of expired tokens.

Value

For adls_filesystem and create_adls_filesystem, an S3 object representing an existing or created filesystem respectively.

For list_adls_filesystems, a list of such objects.

See Also

storage_endpoint, az_storage, storage_container

Examples

```r
## Not run:
endp <- adls_endpoint("https://mystorage.dfs.core.windows.net/", key="access_key")

# list ADLSgen2 filesystems
list_adls_filesystems(endp)

# get, create, and delete a filesystem
adls_filesystem(endp, "myfs")
create_adls_filesystem(endp, "newfs")
delete_adls_filesystem(endp, "newfs")

# alternative way to do the same
adls_filesystem("https://mystorage.dfs.core.windows.net/myfs", key="access_key")
create_adls_filesystem("https://mystorage.dfs.core.windows.net/newfs", key="access_key")
delete_adls_filesystem("https://mystorage.dfs.core.windows.net/newfs", key="access_key")
```

## End(Not run)
Description

Class representing a storage account, exposing methods for working with it.

Methods

The following methods are available, in addition to those provided by the `AzureRMR::az_resource` class:

- `new(...)`: Initialize a new storage object. See 'Initialization'.
- `list_keys()`: Return the access keys for this account.
- `get_account_sas(...)`: Return an account shared access signature (SAS). See 'Creating a shared access signature' below.
- `get_user_delegation_key(...)`: Returns a key that can be used to construct a user delegation SAS.
- `get_user_delegation_sas(...)`: Return a user delegation SAS.
- `revoke_user_delegation_keys()`: Revokes all user delegation keys for the account. This also renders all SAS’s obtained via such keys invalid.
- `get_blob_endpoint(key,sas)`: Return the account's blob storage endpoint, along with an access key and/or a SAS. See 'Endpoints' for more details
- `get_file_endpoint(key,sas)`: Return the account's file storage endpoint.
- `regen_key(key)`: Regenerates (creates a new value for) an access key. The argument key can be 1 or 2.

Initialization

Initializing a new object of this class can either retrieve an existing storage account, or create a account on the host. Generally, the best way to initialize an object is via the `get_storage_account`, `create_storage_account` or `list_storage_accounts` methods of the `az_resource_group` class, which handle the details automatically.

Creating a shared access signature

Note that you don’t need to worry about this section if you have been given a SAS, and only want to use it to access storage.

AzureStor supports generating two kinds of SAS: account and user delegation, with the latter applying only to blob and ADLS2 storage. To create an account SAS, call the `get_account_sas()` method. This has the following signature:

```R
get_account_sas(key=self$list_keys()[1], start=NULL, expiry=NULL, services="bqtf", permissions="rl", resource_types="sco", ip=NULL, protocol=NULL)
```
To create a user delegation SAS, you must first create a user delegation key. This takes the place of the account’s access key in generating the SAS. The `get_user_delegation_key()` method has the following signature:

```r
get_user_delegation_key(token=self$token, key_start=NULL, key_expiry=NULL)
```

Once you have a user delegation key, you can use it to obtain a user delegation sas. The `get_user_delegation_sas()` method has the following signature:

```r
get_user_delegation_sas(key, resource, start=NULL, expiry=NULL, permissions="rl", resource_types="c", ip=NULL, protocol=NULL, snapshot_time=NULL)
```

To invalidate all user delegation keys, as well as the SAS’s generated with them, call the `revoke_user_delegation_keys()` method. This has the following signature:

```r
revoke_user_delegation_keys()
```

See the [Shared access signatures](#) page for more information about this topic.

**Endpoints**

The client-side interaction with a storage account is via an endpoint. A storage account can have several endpoints, one for each type of storage supported: blob, file, queue and table.

The client-side interface in AzureStor is implemented using S3 classes. This is for consistency with other data access packages in R, which mostly use S3. It also emphasises the distinction between Resource Manager (which is for interacting with the storage account itself) and the client (which is for accessing files and data stored in the account).

To create a storage endpoint independently of Resource Manager (for example if you are a user without admin or owner access to the account), use the `blob_endpoint` or `file_endpoint` functions.

If a storage endpoint is created without an access key and SAS, only public (anonymous) access is possible.

`blob_endpoint`, `file_endpoint`, `create_storage_account`, `get_storage_account`, `delete_storage_account`, `Date`, `POSIXt`, Azure Storage Provider API reference, Azure Storage Services API reference, Create an account SAS, Create a user delegation SAS

**Examples**

```r
## Not run:

# recommended way of retrieving a resource: via a resource group object
stor <- resgroup$get_storage_account("mystorage")

# list account access keys
stor$list_keys()

# regenerate a key
```
blob_container

Operations on a blob endpoint

Description

Get, list, create, or delete blob containers.

Usage

blob_container(endpoint, ...)

## S3 method for class 'character'
blob_container(endpoint, key = NULL, token = NULL,
               sas = NULL, api_version = getOption("azure_storage_api_version"), ...)

## S3 method for class 'blob_endpoint'
blob_container(endpoint, name, ...)

## S3 method for class 'blob_container'
print(x, ...)

list_blob_containers(endpoint, ...)

## S3 method for class 'character'
list_blob_containers(endpoint, key = NULL,
                      token = NULL, sas = NULL,
                      api_version = getOption("azure_storage_api_version"), ...)

## S3 method for class 'blob_endpoint'
list_blob_containers(endpoint, ...)

create_blob_container(endpoint, ...)

## S3 method for class 'character'
create_blob_container(endpoint, key = NULL,
                       token = NULL, sas = NULL,
                       api_version = getOption("azure_storage_api_version"), ...)

## S3 method for class 'blob_container'
create_blob_container(endpoint, ...)

## S3 method for class 'blob_endpoin'
create_blob_container(endpoint, name,
public_access = c("none", "blob", "container"), ...)
delete_blob_container(endpoint, ...)

## S3 method for class 'character'
delete_blob_container(endpoint, key = NULL,
token = NULL, sas = NULL,
api_version = getOption("azure_storage_api_version"), ...)

## S3 method for class 'blob_container'
delete_blob_container(endpoint, name, confirm = TRUE, lease = NULL, ...)

details

either a blob endpoint object as created by storage_endpoint, or a character
string giving the URL of the endpoint.

... further arguments passed to lower-level functions.

decies if an endpoint object is not supplied, authentication credentials: either an access
key, an Azure Active Directory (AAD) token, or a SAS, in that order of priority.
If no authentication credentials are provided, only public (anonymous) access to
the share is possible.

api_version If an endpoint object is not supplied, the storage API version to use when interacting with the host. Currently defaults to "2019-07-07".

name The name of the blob container to get, create, or delete.
x For the print method, a blob container object.

public_access For creating a container, the level of public access to allow.
confirm For deleting a container, whether to ask for confirmation.

lease For deleting a leased container, the lease ID.

details

You can call these functions in a couple of ways: by passing the full URL of the share, or by passing
the endpoint object and the name of the container as a string.

If authenticating via AAD, you can supply the token either as a string, or as an object of class
AzureToken, created via AzureRM::get_azure_token. The latter is the recommended way of doing
it, as it allows for automatic refreshing of expired tokens.
Value

For `blob_container` and `create_blob_container`, an S3 object representing an existing or created container respectively.

For `list_blob_containers`, a list of such objects.

See Also

`storage_endpoint`, `az_storage`, `storage_container`

Examples

```r
## Not run:

endp <- blob_endpoint("https://mystorage.blob.core.windows.net/", key="access_key")

# list containers
list_blob_containers(endp)

# get, create, and delete a container
blob_container(endp, "mycontainer")
create_blob_container(endp, "newcontainer")
delete_blob_container(endp, "newcontainer")

# alternative way to do the same
blob_container("https://mystorage.blob.core.windows.net/mycontainer", key="access_key")
create_blob_container("https://mystorage.blob.core.windows.net/newcontainer", key="access_key")
delete_blob_container("https://mystorage.blob.core.windows.net/newcontainer", key="access_key")

# authenticating via AAD
token <- AzureRMR::get_azure_token(resource="https://storage.azure.com/",
                                    tenant="myaadtenant",
                                    app="myappid",
                                    password="mypassword")
blob_container("https://mystorage.blob.core.windows.net/mycontainer", token=token)

## End(Not run)
```

---

call_azcopy

Call the azcopy file transfer utility

Description

Call the azcopy file transfer utility

Usage

```r
call_azcopy(..., env = NULL,
          silent = getOption("azure_storage_azcopy_silent", FALSE))
```
Arguments

... Arguments to pass to AzCopy on the commandline. If no arguments are supplied, a help screen is printed.

env A named character vector of environment variables to set for AzCopy.

silent Whether to print the output from AzCopy to the screen; also sets whether an error return code from AzCopy will be propagated to an R error. Defaults to the value of the azure_storage_azcopy_silent option, or FALSE if this is unset.

Details

AzureStor has the ability to use the Microsoft AzCopy commandline utility to transfer files. To enable this, ensure the processx package is installed and set the argument use_azcopy=TRUE in any call to an upload or download function; AzureStor will then call AzCopy to perform the file transfer rather than relying on its own code. You can also call AzCopy directly with the call_azcopy function.

AzureStor requires version 10 or later of AzCopy. The first time you try to run it, AzureStor will check that the version of AzCopy is correct, and throw an error if it is version 8 or earlier.

The AzCopy utility must be in your path for AzureStor to find it. Note that unlike earlier versions, Azcopy 10 is a single, self-contained binary file that can be placed in any directory.

Value

A list, invisibly, with the following components:

- status: The exit status of the AzCopy command. If this is NA, then the process was killed and had no exit status.
- stdout: The standard output of the command.
- stderr: The standard error of the command.
- timeout: Whether AzCopy was killed because of a timeout.

AzCopy GitHub repo

Examples

```r
## Not run:
endp <- storage_endpoint("https://mystorage.blob.core.windows.net", sas="mysas")
cont <- storage_container(endp, "mycontainer")

# print various help screens
call_azcopy("help")
call_azcopy("help", "copy")
```
# calling azcopy to download a blob
storage_download(cont, "myblob.csv", use_azcopy=TRUE)

# calling azcopy directly (must specify the SAS explicitly in the source URL)
call_azcopy("copy", "https://mystorage.blob.core.windows.net/mycontainer/myblob.csv?mysas", "myblob.csv")

## End(Not run)

---

**copy_url_to_storage**  
*Upload and download generics*

**Description**
Upload and download generics

**Usage**

```
copy_url_to_storage(container, src, dest, ...)
multicopy_url_to_storage(container, src, dest, ...)
```

## S3 method for class 'blob_container'
copy_url_to_storage(container, src, dest, ...)

## S3 method for class 'blob_container'
multicopy_url_to_storage(container, src, dest, ...)

```
storage_upload(container, ...)
```

## S3 method for class 'blob_container'
storage_upload(container, ...)

## S3 method for class 'file_share'
storage_upload(container, ...)

## S3 method for class 'adls_filesystem'
storage_upload(container, ...)

```
storage_multiupload(container, ...)
```

## S3 method for class 'blob_container'
storage_multiupload(container, ...)

## S3 method for class 'file_share'
storage_multiupload(container, ...)

copy_url_to_storage

```r
# S3 method for class 'adls_filesystem'
storage_multiupload(container, ...)

storage_download(container, ...)

# S3 method for class 'blob_container'
storage_download(container, ...)

# S3 method for class 'file_share'
storage_download(container, ...)

# S3 method for class 'adls_filesystem'
storage_download(container, ...)

storage_multidownload(container, ...)

# S3 method for class 'blob_container'
storage_multidownload(container, ...)

# S3 method for class 'file_share'
storage_multidownload(container, ...)

# S3 method for class 'adls_filesystem'
storage_multidownload(container, ...)

download_from_url(src, dest, key = NULL, token = NULL, sas = NULL, ..., overwrite = FALSE)

upload_to_url(src, dest, key = NULL, token = NULL, sas = NULL, ...)
```

**Arguments**

- `container` A storage container object.
- `src, dest` For `upload_to_url` and `download_from_url`, the source and destination files to transfer.
- `...` Further arguments to pass to lower-level functions.
- `key, token, sas` Authentication arguments: an access key, Azure Active Directory (AAD) token or a shared access signature (SAS). If multiple arguments are supplied, a key takes priority over a token, which takes priority over a SAS. For `upload_to_url` and `download_to_url`, you can also provide a SAS as part of the URL itself.
- `overwrite` For downloading, whether to overwrite any destination files that exist.

**Details**

copy_url_to_storage transfers the contents of the file at the specified HTTP[S] URL directly to storage, without requiring a temporary local copy to be made. multicopy_url_to_storage does
the same, for multiple URLs at once. Currently methods for these are only implemented for blob storage.

These functions allow you to transfer files to and from a storage account.

storage_upload, storage_download, storage_multiupload and storage_multidownload take as first argument a storage container, either for blob storage, file storage, or ADLSgen2. They dispatch to the corresponding file transfer functions for the given storage type.

upload_to_url and download_to_url allow you to transfer a file to or from Azure storage, given the URL of the source or destination. The storage details (endpoint, container name, and so on) are obtained from the URL.

By default, the upload and download functions will display a progress bar while they are downloading. To turn this off, use options(azure_storage_progress_bar=FALSE). To turn the progress bar back on, use options(azure_storage_progress_bar=TRUE).

See Also

storage_container, blob_container, file_share, adls_filesystem
download_blob, download_azure_file, download_adls_file, call_azcopy

Examples

## Not run:

```r
# download from blob storage
bl <- storage_endpoint("https://mystorage.blob.core.windows.net/", key="access_key")
cont <- storage_container(bl, "mycontainer")
storage_download(cont, "bigfile.zip", "~/bigfile.zip")

# same download but directly from the URL
download_from_url("https://mystorage.blob.core.windows.net/mycontainer/bigfile.zip",
    "~/bigfile.zip",
    key="access_key")

# upload to ADLSgen2
ad <- storage_endpoint("https://myadls.dfs.core.windows.net/", token=mytoken)
cont <- storage_container(ad, "myfilesystem")
create_storage_dir(cont, "newdir")
storage_upload(cont, "files.zip", "newdir/files.zip")

# same upload but directly to the URL
upload_to_url("files.zip",
    "https://myadls.dfs.core.windows.net/myfilesystem/newdir/files.zip",
    token=mytoken)
```

## End(Not run)
create_storage_account

Create Azure storage account

Description

Method for the AzureRMR::az_resource_group class.

Usage

create_storage_account(name, location, kind = "StorageV2", replication = "Standard_LRS", access_tier = "hot"), https_only = TRUE, hierarchical_namespace_enabled = FALSE, properties = list(), ...)

Arguments

• name: The name of the storage account.
• location: The location/region in which to create the account. Defaults to the resource group location.
• kind: The type of account, either "StorageV2" (the default), "FileStorage" or "BlobStorage".
• replication: The replication strategy for the account. The default is locally-redundant storage (LRS).
• access_tier: The access tier, either "hot" or "cool", for blobs.
• https_only: Whether a HTTPS connection is required to access the storage.
• hierarchical_namespace_enabled: Whether to enable hierarchical namespaces, which are a feature of Azure Data Lake Storage Gen 2 and provide more a efficient way to manage storage. See 'Details' below.
• properties: A list of other properties for the storage account.
• ... Other named arguments to pass to the az_storage initialization function.

Details

This method deploys a new storage account resource, with parameters given by the arguments. A storage account can host multiple types of storage:

• blob storage
• file storage
• table storage
• queue storage
• Azure Data Lake Storage Gen2

Accounts created with kind = "BlobStorage" can only host blob storage, while those with kind = "FileStorage" can only host file storage. Accounts with kind = "StorageV2" can host all types of storage. Currently, AzureStor provides an R interface to ADLSgen2, blob and file storage.

Currently (as of October 2019), if hierarchical namespaces are enabled, the blob API for the account is disabled. The blob endpoint is still accessible, but blob operations on the endpoint will fail. Full interoperability between blobs and ADLSgen2 is planned for later in 2019.
Value

An object of class `az_storage` representing the created storage account.

See Also

`get_storage_account`, `delete_storage_account`, `az_storage`

Azure Storage documentation, Azure Storage Provider API reference, Azure Data Lake Storage hierarchical namespaces

Examples

```r
## Not run:

rg <- AzureRMR::az_rm$
    new(tenant="myaadtenant.onmicrosoft.com", app="app_id", password="password")$
    get_subscription("subscription_id")$
    get_resource_group("rgname")

# create a new storage account
rg$create_storage_account("mystorage", kind="StorageV2")

# create a blob storage account in a different region
rg$create_storage_account("myblobstorage",
    location="australiasoutheast",
    kind="BlobStorage")

## End(Not run)
```

---

delete_storage_account

*Delete an Azure storage account*

Description

Method for the `AzureRMR::az_resource_group` class.

Usage

delete_storage_account(name, confirm=TRUE, wait=FALSE)

Arguments

- name: The name of the storage account.
- confirm: Whether to ask for confirmation before deleting.
- wait: Whether to wait until the deletion is complete.
do_container_op

Value
NULL on successful deletion.

See Also
create_storage_account, get_storage_account, az_storage, Azure Storage Provider API reference

Examples
## Not run:
rg <- AzureRMR::az_rm$
    new(tenant="myaadtenant.onmicrosoft.com", app="app_id", password="password")$
    get_subscription("subscription_id")$
    get_resource_group("rgname")

# delete a storage account
rg$delete_storage_account("mystorage")

## End(Not run)

do_container_op

Carry out operations on a storage account container or endpoint

Description
Carry out operations on a storage account container or endpoint

Usage

do_container_op(container, operation = ",", options = list(),
    headers = list(), http_verb = "GET", ...)

call_storage_endpoint(endpoint, path, options = list(), headers = list(),
    body = NULL, ..., http_verb = c("GET", "DELETE", "PUT", "POST", "HEAD",
    "PATCH"), http_status_handler = c("stop", "warn", "message", "pass"),
    timeout = getOption("azure_storage_timeout"), progress = NULL,
    return_headers = (http_verb == "HEAD"))

Arguments

  container, endpoint
    For do_container_op, a storage container object (inheriting from storage_container).
    For call_storage_endpoint, a storage endpoint object (inheriting from storage_endpoint).

  operation
    The container operation to perform, which will form part of the URL path.

  options
    A named list giving the query parameters for the operation.
headers  A named list giving any additional HTTP headers to send to the host. Note that AzureStor will handle authentication details, so you don’t have to specify these here.

http_verb  The HTTP verb as a string, one of GET, DELETE, PUT, POST, HEAD or PATCH.

...  Any additional arguments to pass to httr::VERB.

path  The path component of the endpoint call.

body  The request body for a PUT/POST/PATCH call.

http_status_handler  The R handler for the HTTP status code of the response. "stop", "warn" or "message" will call the corresponding handlers in httr, while "pass" ignores the status code. The latter is primarily useful for debugging purposes.

timeout  Optionally, the number of seconds to wait for a result. If the timeout interval elapses before the storage service has finished processing the operation, it returns an error. The default timeout is taken from the system option azure_storage_timeout; if this is NULL it means to use the service default.

progress  Used by the file transfer functions, to display a progress bar.

return_headers  Whether to return the (parsed) response headers, rather than the body. Ignored if http_status_handler="pass".

Details

These functions form the low-level interface between R and the storage API. do_container_op constructs a path from the operation and the container name, and passes it and the other arguments to call_storage_endpoint.

Value

Based on the http_status_handler and return_headers arguments. If http_status_handler is "pass", the entire response is returned without modification.

If http_status_handler is one of "stop", "warn" or "message", the status code of the response is checked, and if an error is not thrown, the parsed headers or body of the response is returned. An exception is if the response was written to disk, as part of a file download; in this case, the return value is NULL.

Examples

## Not run:

# get the metadata for a blob
bl_endp <- blob_endpoint("storage_acct_url", key="key")
cont <- storage_container(bl_endp, "containername")
do_container_op(cont, "filename.txt", options=list(comp="metadata"), http_verb="HEAD")

## End(Not run)

---

**file_share**  
*Operations on a file endpoint*

**Description**

Get, list, create, or delete file shares.

**Usage**

```r
file_share(endpoint, ...)
## S3 method for class 'character'
file_share(endpoint, key = NULL, token = NULL,
  sas = NULL, api_version = getOption("azure_storage_api_version"), ...)

## S3 method for class 'file_endpoint'
file_share(endpoint, name, ...)

## S3 method for class 'file_share'
print(x, ...)
list_file_shares(endpoint, ...)
## S3 method for class 'character'
list_file_shares(endpoint, key = NULL, token = NULL,
  sas = NULL, api_version = getOption("azure_storage_api_version"), ...)

## S3 method for class 'file_endpoint'
list_file_shares(endpoint, ...)
create_file_share(endpoint, ...)
## S3 method for class 'character'
create_file_share(endpoint, key = NULL, token = NULL,
  sas = NULL, api_version = getOption("azure_storage_api_version"), ...)

## S3 method for class 'file_share'
create_file_share(endpoint, ...)

## S3 method for class 'file_endpoint'
create_file_share(endpoint, name, ...)
```
delete_file_share(endpoint, ...)  

## S3 method for class 'character'
delete_file_share(endpoint, key = NULL, token = NULL,
     sas = NULL, api_version = getOption("azure_storage_api_version"), ...)

## S3 method for class 'file_share'
delete_file_share(endpoint, ...)

## S3 method for class 'file_endpoint'
delete_file_share(endpoint, name, confirm = TRUE, ...)

Arguments

endpoint  Either a file endpoint object as created by storage_endpoint, or a character string
giving the URL of the endpoint.

...  Further arguments passed to lower-level functions.

key, token, sas  If an endpoint object is not supplied, authentication credentials: either an access
    key, an Azure Active Directory (AAD) token, or a SAS, in that order of priority.

api_version  If an endpoint object is not supplied, the storage API version to use when inter-
    acting with the host. Currently defaults to "2019-07-07".

name  The name of the file share to get, create, or delete.

x  For the print method, a file share object.

confirm  For deleting a share, whether to ask for confirmation.

Details

You can call these functions in a couple of ways: by passing the full URL of the share, or by passing
the endpoint object and the name of the share as a string.

Value

For file_share and create_file_share, an S3 object representing an existing or created share
respectively.

For list_file_shares, a list of such objects.

Examples

### Not run:

```r
endp <- file_endpoint("https://mystorage.file.core.windows.net/", key="access_key")
```

# list file shares
list_file_shares(endp)

# get, create, and delete a file share
file_share(endp, "myshare")
create_file_share(endp, "newshare")
delete_file_share(endp, "newshare")

# alternative way to do the same
file_share("https://mystorage.file.file.windows.net/myshare", key="access_key")
create_file_share("https://mystorage.file.core.windows.net/newshare", key="access_key")
delete_file_share("https://mystorage.file.core.windows.net/newshare", key="access_key")

## End(Not run)

---

**get_account_sas**  
Generate shared access signatures

**Description**

The simplest way for a user to access files and data in a storage account is to give them the account’s access key. This gives them full control of the account, and so may be a security risk. An alternative is to provide the user with a shared access signature (SAS), which limits access to specific resources and only for a set length of time. AzureStor supports generating two kinds of SAS: account and user delegation, with the latter applying only to blob and ADLS2 storage.

**Usage**

get_account_sas(account, ...)

# S3 method for class 'az_storage'
get_account_sas(account, key = account$list_keys()[1], ...)

# S3 method for class 'storage_endpoint'
get_account_sas(account, key = account$key, ...)

# Default S3 method:
get_account_sas(account, key, start = NULL,
    expiry = NULL, services = "bqtf", permissions = "rl",
    resource_types = "sco", ip = NULL, protocol = NULL,
    auth_api_version = getOption("azure_storage_api_version"), ...)

generate_user_delegation_key(account, ...)

# S3 method for class 'az_resource'
generate_user_delegation_key(account, token = account$token, ...)

# S3 method for class 'blob_endpoint'
get_user_delegation_key(account,
    token = account$token, key_start = NULL, key_expiry = NULL, ...)

revoke_user_delegation_keys(account)

## S3 method for class 'az_storage'
revoke_user_delegation_keys(account)

get_user_delegation_sas(account, ...)

## S3 method for class 'az_storage'
get_user_delegation_sas(account, key, ...)

## S3 method for class 'blob_endpoint'
get_user_delegation_sas(account, key, ...)

## Default S3 method:
get_user_delegation_sas(account, key, resource,
    start = NULL, expiry = NULL, permissions = "rl",
    resource_types = "c", ip = NULL, protocol = NULL,
    snapshot_time = NULL,
    auth_api_version = getOption("azure_storage_api_version"), ...)

Arguments

account An object representing a storage account. Depending on the generic, this can
    be one of the following: an Azure resource object (of class az_storage); a
    client storage endpoint (of class storage_endpoint); a blob storage endpoint
    (of class blob_endpoint); or a string with the name of the account.

... Arguments passed to lower-level functions.

key For get_account_sas, the account key, which controls full access to the storage
    account. For get_user_delegation_sas, a user delegation key, as obtained
    from get_user_delegation_key.

start, expiry The start and end dates for the account or user delegation SAS. These should be
    Date or POSIXct values, or strings coercible to such. If not supplied, the default
    is to generate start and expiry values for a period of 8 hours, starting from 15
    minutes before the current time.

services For get_account_sas, the storage service(s) for which the SAS is valid. De-
   faults to bqtf, meaning blob (including ADLS2), queue, table and file storage.

permissions For get_account_sas and get_user_delegation_sas, the permissions that
    the SAS grants. The default rl (read and list) essentially means read-only ac-
    cess.

resource_types The resource types for which the SAS is valid. For get_account_sas the de-
    fault is sco meaning service, container and object. For get_user_delegation_sas
    the default is c meaning container-level access (including blobs within the con-
    tainer).
**get_account_sas**

**ip**
The IP address(es) or IP address range(s) for which the SAS is valid. The default is not to restrict access by IP.

**protocol**
The protocol required to use the SAS. Possible values are https meaning HTTPS-only, or https,http meaning HTTP is also allowed. Note that the storage account itself may require HTTPS, regardless of what the SAS allows.

**auth_api_version**
The storage API version to use for authenticating.

**token**
For get_user_delegation_key, an AAD token from which to obtain user details. The token must have https://storage.azure.com as its audience.

**key_start, key_expiry**
For get_user_delegation_key, the start and end dates for the user delegation key.

**resource**
For get_user_delegation_sas, the resource for which the SAS is valid. This can be either the name of a blob container, or a blob. If the latter, it should include the container as well (containername/blobname).

**snapshot_time**
For get_user_delegation_sas, the blob snapshot for which the SAS is valid. Only required if resource_types="bs".

**Details**

Listed here are S3 generics and methods to obtain a SAS for accessing storage; in addition, the az_storage resource class has R6 methods for get_account_sas, get_user_delegation_key and revoke_user_delegation_keys which simply call the corresponding S3 method.

Note that you don’t need to worry about these methods if you have been given a SAS, and only want to use it to access a storage account.

An account SAS is secured with the storage account key. An account SAS delegates access to resources in one or more of the storage services. All of the operations available via a user delegation SAS are also available via an account SAS. You can also delegate access to read, write, and delete operations on blob containers, tables, queues, and file shares. To obtain an account SAS, call get_account_sas.

A user delegation SAS is a SAS secured with Azure AD credentials. It’s recommended that you use Azure AD credentials when possible as a security best practice, rather than using the account key, which can be more easily compromised. When your application design requires shared access signatures, use Azure AD credentials to create a user delegation SAS for superior security.

Every SAS is signed with a key. To create a user delegation SAS, you must first request a user delegation key, which is then used to sign the SAS. The user delegation key is analogous to the account key used to sign a service SAS or an account SAS, except that it relies on your Azure AD credentials. To request the user delegation key, call get_user_delegation_key. With the user delegation key, you can then create the SAS with get_user_delegation_sas.

To invalidate all user delegation keys, as well as the SAS’s generated with them, call revoke_user_delegation_keys.

See the examples and Microsoft Docs pages below for how to specify arguments like the services, permissions, and resource types. Also, while not explicitly mentioned in the documentation, ADLS-gen2 storage can use any SAS that is valid for blob storage.
get_storage_account

Get existing Azure storage account(s)

description

Methods for the AzureRMR::az_resource_group and AzureRMR::az_subscription classes.

Usage

get_storage_account(name)
list_storage_accounts()
get_storage_metadata

Arguments

- name: For get_storage_account(), the name of the storage account.

Details

The AzureRMR::az_resource_group class has both get_storage_account() and list_storage_accounts() methods, while the AzureRMR::az_subscription class only has the latter.

Value

For get_storage_account(), an object of class az_storage representing the storage account.
For list_storage_accounts(), a list of such objects.

See Also

create_storage_account, delete_storage_account, az_storage, Azure Storage Provider API reference

Examples

## Not run:

rg <- AzureRMR::az_rm$
  new(tenant="myaadtenant.onmicrosoft.com", app="app_id", password="password")$
  get_subscription("subscription_id")$
  get_resource_group("rgname")$

# get a storage account
rg$get_storage_account("mystorage")

## End(Not run)

get_storage_metadata

Get/set user-defined metadata for a storage object

Description

Get/set user-defined metadata for a storage object

Usage

get_storage_metadata(object, ...)

## S3 method for class 'blob_container'
get_storage_metadata(object, blob, ...)

## S3 method for class 'file_share'
get_storage_metadata(object, file, isdir, ...)
## S3 method for class 'adls_filesystem'
get_storage_metadata(object, file, ...)

set_storage_metadata(object, ...)

## S3 method for class 'blob_container'
set_storage_metadata(object, blob, ..., keep_existing = TRUE)

## S3 method for class 'file_share'
set_storage_metadata(object, file, isdir, ..., keep_existing = TRUE)

## S3 method for class 'adls_filesystem'
set_storage_metadata(object, file, ..., keep_existing = TRUE)

### Arguments
- **object**
  A blob container, file share or ADLS filesystem object.
- **...**
  For the metadata setters, name-value pairs to set as metadata for a blob or file.
- **blob, file**
  Optionally the name of an individual blob, file or directory within a container.
- **isdir**
  For the file share method, whether the file argument is a file or directory. If omitted, get_storage_metadata will auto-detect the type; however this can be slow, so supply this argument if possible.
- **keep_existing**
  For the metadata setters, whether to retain existing metadata information.

### Details
These methods let you get and set user-defined properties (metadata) for storage objects.

### Value
get_storage_metadata returns a named list of metadata properties. If the blob or file argument is present, the properties will be for the blob/file specified. If this argument is omitted, the properties will be for the container itself.

set_storage_metadata returns the same list after setting the object’s metadata, invisibly.

### See Also
- `blob_container`, `file_share`, `adls_filesystem`
- `get_storage_properties` for standard properties

### Examples
```r
## Not run:
fs <- storage_container("https://mystorage.dfs.core.windows.net/myshare", key="access_key")
create_storage_dir("newdir")
storage_upload(share, "iris.csv", "newdir/iris.csv")
```
```r
set_storage_metadata(fs, "newdir/iris.csv", name1="value1")
# will be list(name1="value1")
get_storage_metadata(fs, "newdir/iris.csv")

set_storage_metadata(fs, "newdir/iris.csv", name2="value2")
# will be list(name1="value1", name2="value2")
get_storage_metadata(fs, "newdir/iris.csv")

set_storage_metadata(fs, "newdir/iris.csv", name3="value3", keep_existing=FALSE)
# will be list(name3="value3")
get_storage_metadata(fs, "newdir/iris.csv")

# deleting all metadata
set_storage_metadata(fs, "newdir/iris.csv", keep_existing=FALSE)
```

```r
get_storage_properties
```

Get storage properties for an object

Description

Get storage properties for an object

Usage

```r
get_storage_properties(object, ...)
```

## S3 method for class 'blob_container'
```r
get_storage_properties(object, blob, ...)
```

## S3 method for class 'file_share'
```r
get_storage_properties(object, file, isdir, ...)
```

## S3 method for class 'adls_filesystem'
```r
get_storage_properties(object, file, ...)
```

get_adls_file_acl(filesystem, file)

get_adls_file_status(filesystem, file)

Arguments

<table>
<thead>
<tr>
<th>argument</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>object</td>
<td>A blob container, file share, or ADLS filesystem object.</td>
</tr>
<tr>
<td>...</td>
<td>For compatibility with the generic.</td>
</tr>
</tbody>
</table>
list_adls_files

operations on an Azure Data Lake Storage Gen2 filesystem

Description

Upload, download, or delete a file; list files in a directory; create or delete directories; check file existence.

Value

get_storage_properties returns a list describing the object properties. If the blob or file argument is present for the container methods, the properties will be for the blob/file specified. If this argument is omitted, the properties will be for the container itself.
get_adls_file_acl returns a string giving the ADLSgen2 ACL for the file.
get_adls_file_status returns a list of ADLSgen2 system properties for the file.

See Also

blob_container, file_share, adls_filesystem

get_storage_metadata for getting and setting user-defined properties (metadata)

Examples

## Not run:

```r
fs <- storage_container("https://mystorage.dfs.core.windows.net/myshare", key="access_key")
create_storage_dir("newdir")
storage_upload(share, "iris.csv", "newdir/iris.csv")

get_storage_properties(fs)
get_storage_properties(fs, "newdir")
get_storage_properties(fs, "newdir/iris.csv")

# these are ADLS only
get_adls_file_acl(fs, "newdir/iris.csv")
get_adls_file_status(fs, "newdir/iris.csv")

## End(Not run)
```
list_adls_files

Usage

list_adls_files(filesystem, dir = "/", info = c("all", "name"), recursive = FALSE)

multiupload_adls_file(filesystem, src, dest, recursive = FALSE, blocksize = 2^22, lease = NULL, put_md5 = FALSE, use_azcopy = FALSE, max_concurrent_transfers = 10)

upload_adls_file(filesystem, src, dest = basename(src), blocksize = 2^24, lease = NULL, put_md5 = FALSE, use_azcopy = FALSE)

multidownload_adls_file(filesystem, src, dest, recursive = FALSE, blocksize = 2^24, overwrite = FALSE, check_md5 = FALSE, use_azcopy = FALSE, max_concurrent_transfers = 10)

download_adls_file(filesystem, src, dest = basename(src), blocksize = 2^24, overwrite = FALSE, check_md5 = FALSE, use_azcopy = FALSE)

delete_adls_file(filesystem, file, confirm = TRUE)

create_adls_dir(filesystem, dir)

delete_adls_dir(filesystem, dir, recursive = FALSE, confirm = TRUE)

adls_file_exists(filesystem, file)

Arguments

filesystem: An ADLSgen2 filesystem object.
dir, file: A string naming a directory or file respectively.
info: Whether to return names only, or all information in a directory listing.
recursive: For the multiupload/download functions, whether to recursively transfer files in subdirectories. For list_adls_files, and delete_adls_dir, whether the operation should recurse through subdirectories. For delete_adls_dir, this must be TRUE to delete a non-empty directory.
src, dest: The source and destination paths/files for uploading and downloading. See 'Details' below.
blocksize: The number of bytes to upload/download per HTTP(S) request.
lease: The lease for a file, if present.
put_md5: For uploading, whether to compute the MD5 hash of the file(s). This will be stored as part of the file’s properties.
use_azcopy: Whether to use the AzCopy utility from Microsoft to do the transfer, rather than doing it in R.
max_concurrent_transfers: For multiupload_adls_file and multidownload_adls_file, the maximum number of concurrent file transfers. Each concurrent file transfer requires a separate R process, so limit this if you are low on memory.
overwrite  When downloading, whether to overwrite an existing destination file.
check_md5  For downloading, whether to verify the MD5 hash of the downloaded file(s).
This requires that the file’s Content-MD5 property is set. If this is TRUE and the
Content-MD5 property is missing, a warning is generated.
countinue  Whether to ask for confirmation on deleting a file or directory.

Details
upload_adls_file and download_adls_file are the workhorse file transfer functions for ADLS-
gen2 storage. They each take as inputs a single filename as the source for uploading/downloading,
and a single filename as the destination. Alternatively, for uploading, src can be a textConnection
or rawConnection object; and for downloading, dest can be NULL or a rawConnection object. If
dest is NULL, the downloaded data is returned as a raw vector, and if a raw connection, it will be
placed into the connection. See the examples below.
multiupload_adls_file and multidownload_adls_file are functions for uploading and down-
loading multiple files at once. They parallelise file transfers by using the background process pool
provided by AzureRMR, which can lead to significant efficiency gains when transferring many
small files. There are two ways to specify the source and destination for these functions:
• Both src and dest can be vectors naming the individual source and destination pathnames.
• The src argument can be a wildcard pattern expanding to one or more files, with dest naming
  a destination directory. In this case, if recursive is true, the file transfer will replicate the
  source directory structure at the destination.
upload_adls_file and download_adls_file can display a progress bar to track the file transfer.
You can control whether to display this with options(azure_storage_progress_bar=TRUE|FALSE);
the default is TRUE.

Value
For list_adls_files, if info="name", a vector of file/directory names. If info="all", a data
frame giving the file size and whether each object is a file or directory.
For download_adls_file, if dest=NULL, the contents of the downloaded file as a raw vector.
For adls_file_exists, either TRUE or FALSE.

AzCopy
upload_azure_file and download_azure_file have the ability to use the AzCopy commandline
utility to transfer files, instead of native R code. This can be useful if you want to take advantage
of AzCopy’s logging and recovery features; it may also be faster in the case of transferring a very
large number of small files. To enable this, set the use_azcopy argument to TRUE.
Note that AzCopy only supports SAS and AAD (OAuth) token as authentication methods. AzCopy
also expects a single filename or wildcard spec as its source/destination argument, not a vector of
filenames or a connection.

adls_filesystem, az_storage, storage_download, call_azcopy
Examples

```r
## Not run:

fs <- adls_filesystem("https://mystorage.dfs.core.windows.net/myfilesystem", key="access_key")
list_adls_files(fs, "/")
list_adls_files(fs, "/", recursive=TRUE)
create_adls_dir(fs, "/newdir")
upload_adls_file(fs, "/-bigfile.zip", dest="/newdir/bigfile.zip")
download_adls_file(fs, "/-newdir/bigfile.zip", dest="/-bigfile_downloaded.zip")
delete_adls_file(fs, "/-newdir/bigfile.zip")
delete_adls_dir(fs, "/-newdir")

# uploading/downloading multiple files at once
multiupload_adls_file(fs, "/data/logfiles/*.zip")
multidownload_adls_file(fs, "/monthly/jan*.x", "/data/january")

# you can also pass a vector of file/pathnames as the source and destination
src <- c("file1.csv", "file2.csv", "file3.csv")
dest <- paste0("uploaded ", src)
multiupload_adls_file(share, src, dest)

# uploading serialized R objects via connections
json <- jsonlite::toJSON(iris, pretty=TRUE, auto_unbox=TRUE)
con <- textConnection(json)
upload_adls_file(fs, con, "iris.json")
rds <- serialize(iris, NULL)
con <- rawConnection(rds)
upload_adls_file(fs, con, "iris.rds")

# downloading files into memory: as a raw vector, and via a connection
rawvec <- download_adls_file(fs, "iris.json", NULL)
rawToChar(rawvec)
con <- rawConnection(raw(0), "r+")
download_adls_file(fs, "iris.rds", con)
unserialize(con)

## End(Not run)
```
Description

Upload, download, or delete a file; list files in a directory; create or delete directories; check file existence.

Usage

list_azure_files(share, dir = "/", info = c("all", "name"),
                  prefix = NULL, recursive = FALSE)

upload_azure_file(share, src, dest = basename(src), create_dir = FALSE,
                   blocksize = 2^22, put_md5 = FALSE, use_azcopy = FALSE)

multiupload_azure_file(share, src, dest, recursive = FALSE,
                        create_dir = recursive, blocksize = 2^22, put_md5 = FALSE,
                        use_azcopy = FALSE, max_concurrent_transfers = 10)

download_azure_file(share, src, dest = basename(src), blocksize = 2^22,
                   overwrite = FALSE, check_md5 = FALSE, use_azcopy = FALSE)

multidownload_azure_file(share, src, dest, recursive = FALSE,
                         blocksize = 2^22, overwrite = FALSE, check_md5 = FALSE,
                         use_azcopy = FALSE, max_concurrent_transfers = 10)

delete_azure_file(share, file, confirm = TRUE)

create_azure_dir(share, dir, recursive = FALSE)

delete_azure_dir(share, dir, recursive = FALSE, confirm = TRUE)

azure_file_exists(share, file)

Arguments

share A file share object.
dir, file A string naming a directory or file respectively.
info Whether to return names only, or all information in a directory listing.
prefix For list_azure_files, filters the result to return only files and directories
         whose name begins with this prefix.
recursive For the multiupload/download functions, whether to recursively transfer files
            in subdirectories. For list_azure_dir, whether to include the contents of any
            subdirectories in the listing. For create_azure_dir, whether to recursively cre-
            ate each component of a nested directory path. For delete_azure_dir, whether
            to delete a subdirectory’s contents first (not yet supported). Note that in all cases
            this can be slow, so try to use a non-recursive solution if possible.
src, dest The source and destination files for uploading and downloading. See ’Details’
            below.
For the uploading functions, whether to create the destination directory if it doesn’t exist. Again for the file storage API this can be slow, hence is optional.

The number of bytes to upload/download per HTTP(S) request.

For uploading, whether to compute the MD5 hash of the file(s). This will be stored as part of the file’s properties.

Whether to use the AzCopy utility from Microsoft to do the transfer, rather than doing it in R.

For multiupload_azure_file and multidownload_azure_file, the maximum number of concurrent file transfers. Each concurrent file transfer requires a separate R process, so limit this if you are low on memory.

When downloading, whether to overwrite an existing destination file.

For downloading, whether to verify the MD5 hash of the downloaded file(s). This requires that the file’s Content-MD5 property is set. If this is TRUE and the Content-MD5 property is missing, a warning is generated.

Whether to ask for confirmation on deleting a file or directory.

upload_azure_file and download_azure_file are the workhorse file transfer functions for file storage. They each take as inputs a single filename as the source for uploading/downloading, and a single filename as the destination. Alternatively, for uploading, 

src can be a textConnection or rawConnection object; and for downloading, dest can be NULL or a rawConnection object. If dest is NULL, the downloaded data is returned as a raw vector, and if a raw connection, it will be placed into the connection. See the examples below.

multiupload_azure_file and multidownload_azure_file are functions for uploading and downloading multiple files at once. They parallelise file transfers by using the background process pool provided by AzureRMR, which can lead to significant efficiency gains when transferring many small files. There are two ways to specify the source and destination for these functions:

- Both src and dest can be vectors naming the individual source and destination pathnames.
- The src argument can be a wildcard pattern expanding to one or more files, with dest naming a destination directory. In this case, if recursive is true, the file transfer will replicate the source directory structure at the destination.

upload_azure_file and download_azure_file can display a progress bar to track the file transfer. You can control whether to display this with options(azure_storage_progress_bar=TRUE|FALSE); the default is TRUE.

For list_azure_files, if info="name", a vector of file/directory names. If info="all", a data frame giving the file size and whether each object is a file or directory.

For download_azure_file, if dest=NULL, the contents of the downloaded file as a raw vector.

For azure_file_exists, either TRUE or FALSE.
AzCopy

`upload_azure_file` and `download_azure_file` have the ability to use the AzCopy commandline utility to transfer files, instead of native R code. This can be useful if you want to take advantage of AzCopy's logging and recovery features; it may also be faster in the case of transferring a very large number of small files. To enable this, set the `use_azcopy` argument to `TRUE`.

Note that AzCopy only supports SAS and AAD (OAuth) token as authentication methods. AzCopy also expects a single filename or wildcard spec as its source/destination argument, not a vector of filenames or a connection.

AzCopy version 10 on GitHub

Examples

```r
## Not run:
share <- file_share("https://mystorage.file.core.windows.net/myshare", key="access_key")
list_azure_files(share, "/")
list_azure_files(share, "/", recursive=TRUE)
create_azure_dir(share, "/newdir")
upload_azure_file(share, "~/bigfile.zip", dest="/newdir/bigfile.zip")
download_azure_file(share, "/newdir/bigfile.zip", dest="~/bigfile_downloaded.zip")
delete_azure_file(share, "/newdir/bigfile.zip")
delete_azure_dir(share, "/newdir")

# uploading/downloading multiple files at once
multiupload_azure_file(share, "/data/logfiles/*.zip")
multidownload_azure_file(share, "/monthly/jan*.", "/data/january")

# you can also pass a vector of file/pathnames as the source and destination
src <- c("file1.csv", "file2.csv", "file3.csv")
dest <- paste0("uploaded_", src)
multiupload_azure_file(share, src, dest)

# uploading serialized R objects via connections
json <- jsonlite::toJSON(iris, pretty=TRUE, auto_unbox=TRUE)
con <- textConnection(json)
upload_azure_file(share, con, "iris.json")

rds <- serialize(iris, NULL)
con <- rawConnection(rds)
upload_azure_file(share, con, "iris.rds")

# downloading files into memory: as a raw vector, and via a connection
rawvec <- download_azure_file(share, "iris.json", NULL)
```
rawToChar(rawvec)
con <- rawConnection(raw(0), "r+")
download_azure_file(share, "iris.rds", con)
unserialize(con)

## End(Not run)

---

### list_blobs

**Operations on a blob container or blob**

**Description**

Upload, download, or delete a blob; list blobs in a container; create or delete directories; check blob availability.

**Usage**

```r
list_blobs(container, dir = "/", info = c("partial", "name", "all"),
   prefix = NULL, recursive = TRUE)
```

```r
upload_blob(container, src, dest = basename(src), type = c("BlockBlob",
   "AppendBlob"), blocksize = if (type == "BlockBlob") 2^24 else 2^22,
   lease = NULL, put_md5 = FALSE, append = FALSE, use_azcopy = FALSE)
```

```r
multiupload_blob(container, src, dest, recursive = FALSE,
   type = c("BlockBlob", "AppendBlob"), blocksize = if (type == "BlockBlob")
   2^24 else 2^22, lease = NULL, put_md5 = FALSE, append = FALSE,
   use_azcopy = FALSE, max_concurrent_transfers = 10)
```

```r
download_blob(container, src, dest = basename(src), blocksize = 2^24,
   overwrite = FALSE, lease = NULL, check_md5 = FALSE,
   use_azcopy = FALSE)
```

```r
multidownload_blob(container, src, dest, recursive = FALSE,
   blocksize = 2^24, overwrite = FALSE, lease = NULL, check_md5 = FALSE,
   use_azcopy = FALSE, max_concurrent_transfers = 10)
```

```r
delete_blob(container, blob, confirm = TRUE)
```

```r
create_blob_dir(container, dir)
```

```r
delete_blob_dir(container, dir, recursive = FALSE, confirm = TRUE)
```

```r
blob_exists(container, blob)
```

```r
copy_url_to_blob(container, src, dest, lease = NULL, async = FALSE)
```
multicopy_url_to_blob(container, src, dest, lease = NULL, async = FALSE,
max_concurrent_transfers = 10)

Arguments

container  A blob container object.

dir       For list_blobs. A string naming the directory. Note that blob storage does not support real directories; this argument simply filters the result to return only blobs whose names start with the given value.

info      For list_blobs, level of detail about each blob to return: a vector of names only; the name, size, blob type, and whether this blob represents a directory; or all information.

prefix    For list_blobs, an alternative way to specify the directory.

recursive For the multiupload/download functions, whether to recursively transfer files in subdirectories. For list_blobs, whether to include the contents of any subdirectories in the listing. For delete_blob_dir, whether to recursively delete subdirectory contents as well (not yet supported).

type      The source and destination files for uploading and downloading. See ’Details’ below.

src, dest  When uploading, the type of blob to create. Currently only block and append blobs are supported.

blocksize The number of bytes to upload/download per HTTP(S) request.

lease     The lease for a blob, if present.

put_md5   For uploading, whether to compute the MD5 hash of the blob(s). This will be stored as part of the blob’s properties. Only used for block blobs.

append    When uploading, whether to append the uploaded data to the destination blob. Only has an effect if type=”AppendBlob”. If this is FALSE (the default) and the destination append blob exists, it is overwritten. If this is TRUE and the destination does not exist or is not an append blob, an error is thrown.

use_azcopy Whether to use the AzCopy utility from Microsoft to do the transfer, rather than doing it in R.

max_concurrent_transfers For multiupload_blob and multidownload_blob, the maximum number of concurrent file transfers. Each concurrent file transfer requires a separate R process, so limit this if you are low on memory.

overwrite When downloading, whether to overwrite an existing destination file.

check_md5 For downloading, whether to verify the MD5 hash of the downloaded blob(s). This requires that the blob’s Content-MD5 property is set. If this is TRUE and the Content-MD5 property is missing, a warning is generated.

confirm   Whether to ask for confirmation on deleting a blob.

async     For copy_url_to_blob and multicopy_url_to_blob, whether the copy operation should be asynchronous (proceed in the background).
Details

`upload_blob` and `download_blob` are the workhorse file transfer functions for blobs. They each take as inputs a single filename as the source for uploading/downloading, and a single filename as the destination. Alternatively, for uploading, `src` can be a `textConnection` or `rawConnection` object; and for downloading, `dest` can be NULL or a `rawConnection` object. If `dest` is NULL, the downloaded data is returned as a raw vector, and if a raw connection, it will be placed into the connection. See the examples below.

`multiupload_blob` and `multidownload_blob` are functions for uploading and downloading multiple files at once. They parallelise file transfers by using the background process pool provided by AzureRMR, which can lead to significant efficiency gains when transferring many small files.

There are two ways to specify the source and destination for these functions:

- Both `src` and `dest` can be vectors naming the individual source and destination pathnames.
- The `src` argument can be a wildcard pattern expanding to one or more files, with `dest` naming a destination directory. In this case, if `recursive` is true, the file transfer will replicate the source directory structure at the destination.

`upload_blob` and `download_blob` can display a progress bar to track the file transfer. You can control whether to display this with `options(azure_storage_progress_bar=TRUE|FALSE)`; the default is `TRUE`.

`multiupload_blob` can upload files either as all block blobs or all append blobs, but not a mix of both.

`copy_url_to_blob` transfers the contents of the file at the specified HTTP[S] URL directly to blob storage, without requiring a temporary local copy to be made. `multicopy_url_to_blob` does the same, for multiple URLs at once. These functions have a current file size limit of 256MB.

Value

For `list_blobs`, details on the blobs in the container. For `download_blob`, if `dest=NULL`, the contents of the downloaded blob as a raw vector. For `blob_exists` a flag whether the blob exists.

AzCopy

`upload_blob` and `download_blob` have the ability to use the AzCopy commandline utility to transfer files, instead of native R code. This can be useful if you want to take advantage of AzCopy’s logging and recovery features; it may also be faster in the case of transferring a very large number of small files. To enable this, set the `use_azcopy` argument to `TRUE`.

The following points should be noted about AzCopy:

- It only supports SAS and AAD (OAuth) token as authentication methods. AzCopy also expects a single filename or wildcard spec as its source/destination argument, not a vector of filenames or a connection.
- Currently, it does not support appending data to existing blobs.

Directories

Blob storage does not have true directories, instead using filenames containing a separator character (typically '/') to mimic a directory structure. This has some consequences:
• The \texttt{isdir} column in the data frame output of \texttt{list_blobs} is a best guess as to whether an object represents a file or directory, and may not always be correct. Currently, \texttt{list_blobs} assumes that any object with a file size of zero is a directory.

• Zero-length files can cause problems for the blob storage service as a whole (not just AzureStor). Try to avoid uploading such files.

• \texttt{create_blob_dir} and \texttt{delete_blob_dir} function as expected only for accounts with hierarchical namespaces enabled. When this feature is disabled, directories do not exist as objects in their own right: to create a directory, simply upload a blob to that directory. To delete a directory, delete all the blobs within it; as far as the blob storage service is concerned, the directory then no longer exists.

• Similarly, the output of \texttt{list_blobs(recursive=TRUE)} can vary based on whether the storage account has hierarchical namespaces enabled.

\textbf{See Also}

\textbf{Examples}

```r
# Not run:
cont <- blob_container("https://mystorage.blob.core.windows.net/mycontainer", key="access_key")
list_blobs(cont)
upload_blob(cont, "~/bigfile.zip", dest="bigfile.zip")
download_blob(cont, "bigfile.zip", dest="~/bigfile_downloaded.zip")
delete_blob(cont, "bigfile.zip")
```

# uploading/downloading multiple files at once
```
multiupload_blob(cont, "/data/logfiles/*.zip", "/uploaded_data")
multiupload_blob(cont, "myproj/*") # no dest directory uploads to root
multidownload_blob(cont, "jan*.*", "/data/january")
```

# append blob: concatenating multiple files into one
```
upload_blob(cont, "logfile1", "logfile", type="AppendBlob", append=FALSE)
upload_blob(cont, "logfile2", "logfile", type="AppendBlob", append=TRUE)
upload_blob(cont, "logfile3", "logfile", type="AppendBlob", append=TRUE)
```

# you can also pass a vector of file/pathnames as the source and destination
```
src <- c("file1.csv", "file2.csv", "file3.csv")
dest <- paste0("uploaded", , src)
multiupload_blob(cont, src, dest)
```

# uploading serialized R objects via connections
```
json <- jsonlite::toJSON(iris, pretty=TRUE, auto_unbox=TRUE)
con <- textConnection(json)
upload_blob(cont, con, "iris.json")
```
sign_request

```
# download files into memory: as a raw vector, and via a connection
rawvec <- download_blob(cont, "iris.json", NULL)
rawToChar(rawvec)

# copy from a public URL: Iris data from UCI machine learning repository
copy_url_to_blob(cont,
  "iris.csv")
```

## End(Not run)

---

**sign_request**

*Signs a request to the storage REST endpoint with a shared key*

### Description

Signs a request to the storage REST endpoint with a shared key.

### Usage

```
sign_request(endpoint, ...)
```

### Arguments

- **endpoint**: An endpoint object.
- **...**: Further arguments to pass to individual methods.

### Details

This is a generic method to allow for variations in how the different storage services handle key authorisation. The default method works with blob, file and ADLSgen2 storage.

### Value

A named list of request headers. One of these should be the Authorization header containing the request signature.
storage_container

## Description

storage_file_exists(container, file, ...)

## S3 method for class 'blob_container'
storage_file_exists(container, file, ...)

## S3 method for class 'file_share'
storage_file_exists(container, file, ...)

## S3 method for class 'adls_filesystem'
storage_file_exists(container, file, ...)

### Arguments

- **endpoint**: A storage endpoint object, or for the character methods, a string giving the full URL to the container.

- **...**: Further arguments to pass to lower-level functions.

- **name**: For the storage container management methods, a container name.

- **key, token, sas**: For the character methods, authentication credentials for the container: either an access key, an Azure Active Directory (AAD) token, or a SAS. If multiple arguments are supplied, a key takes priority over a token, which takes priority over a SAS.

- **confirm**: For the deletion methods, whether to ask for confirmation first.

- **container**: A storage container object.

- **file, dir**: For the storage object management methods, a file or directory name.
storage_container

Details

These methods provide a framework for all storage management tasks supported by AzureStor. They dispatch to the appropriate functions for each type of storage.

Storage container management methods:

• `storage_container` dispatches to `blob_container`, `file_share` or `adls_filesystem`
• `create_storage_container` dispatches to `create_blob_container`, `create_file_share` or `create_adls_filesystem`
• `delete_storage_container` dispatches to `delete_blob_container`, `delete_file_share` or `delete_adls_filesystem`
• `list_storage_containers` dispatches to `list_blob_containers`, `list_file_shares` or `list_adls_filesystems`

Storage object management methods:

• `list_storage_files` dispatches to `list_blobs`, `list_azure_files` or `list_adls_files`
• `create_storage_dir` dispatches to `create_azure_dir` or `create_adls_dir`; throws an error if passed a blob container
• `delete_storage_dir` dispatches to `delete_azure_dir` or `delete_adls_dir`; throws an error if passed a blob container
• `delete_storage_file` dispatches to `delete_blob`, `delete_azure_file` or `delete_adls_file`

See Also

`storage_endpoint`, `blob_container`, `file_share`, `adls_filesystem`
`list_blobs`, `list_azure_files`, `list_adls_files`

Similar generics exist for file transfer methods; see the page for `storage_download`.

Examples

```r
# storage endpoints for the one account
bl <- storage_endpoint("https://mystorage.blob.core.windows.net/", key="access_key")
fl <- storage_endpoint("https://mystorage.file.core.windows.net/", key="access_key")

list_storage_containers(bl)
list_storage_containers(fl)

# creating containers
cont <- create_storage_container(bl, "newblobcontainer")
fs <- create_storage_container(fl, "newfileshare")

# creating directories (if possible)
create_storage_dir(cont, "newdir")  # will error out
create_storage_dir(fs, "newdir")

# transfer a file
```
### storage_endpoint

Create a storage endpoint object

#### Description
Create a storage endpoint object, for interacting with blob, file, table, queue or ADLSgen2 storage.

#### Usage

```r
storage_endpoint(endpoint, key = NULL, token = NULL, sas = NULL, api_version)
```

```r
blob_endpoint(endpoint, key = NULL, token = NULL, sas = NULL,
api_version = getOption("azure_storage_api_version"))
```

```r
file_endpoint(endpoint, key = NULL, token = NULL, sas = NULL,
api_version = getOption("azure_storage_api_version"))
```

```r
adls_endpoint(endpoint, key = NULL, token = NULL, sas = NULL,
api_version = getOption("azure_adls_api_version"))
```

```r
## S3 method for class 'storage_endpoint'
print(x, ...)
```

```r
## S3 method for class 'adls_endpoint'
print(x, ...)
```

#### Arguments
- **endpoint**
The URL (hostname) for the endpoint. This must be of the form http[s]://[account-name].[type].[core-host-name], where type is one of “dfs” (corresponding to ADLSgen2), "blob", "file", "queue" or "table". On the public Azure cloud, endpoints will be of the form https://[account-name].[type].core.windows.net.

- **key**
The access key for the storage account.

- **token**
an Azure Active Directory (AAD) authentication token. This can be either a string, or an object of class AzureToken created by AzureRMR::get_azure_token. The latter is the recommended way of doing it, as it allows for automatic refreshing of expired tokens.

- **sas**
A shared access signature (SAS) for the account.

- **api_version**
The storage API version to use when interacting with the host. Defaults to "2019-07-07".

- **x**
For the print method, a storage endpoint object.

- **...**
For the print method, further arguments passed to lower-level functions.
storage_endpoint

Details

This is the starting point for the client-side storage interface in AzureRMR. storage_endpoint is a generic function to create an endpoint for any type of Azure storage while adls_endpoint, blob_endpoint and file_endpoint create endpoints for those types.

If multiple authentication objects are supplied, they are used in this order of priority: first an access key, then an AAD token, then a SAS. If no authentication objects are supplied, only public (anonymous) access to the endpoint is possible.

Value

storage_endpoint returns an object of S3 class "adls_endpoint", "blob_endpoint", "file_endpoint", "queue_endpoint" or "table_endpoint" depending on the type of endpoint. All of these also inherit from class "storage_endpoint". adls_endpoint, blob_endpoint and file_endpoint return an object of the respective class.

Note that while endpoint classes exist for all storage types, currently AzureStor only includes methods for interacting with ADLSgen2, blob and file storage.

Storage emulators

AzureStor supports connecting to the Azure SDK and Azurite emulators for blob and queue storage. To connect, pass the full URL of the endpoint, including the account name, to the blob_endpoint and queue_endpoint methods (the latter from the AzureQstor package). The warning about an unrecognised endpoint can be ignored. See the linked pages, and the examples below, for details on how to authenticate with the emulator.

Note that the Azure SDK emulator is no longer being actively developed; it’s recommended to use Azurite for development work.

See Also

create_storage_account, adls_filesystem, create_adls_filesystem, file_share, create_file_share, blob_container, create_blob_container

Examples

## Not run:

# obtaining an endpoint from the storage account resource object
stor <- AzureRMR::get_azure_login()$
get_subscription("sub_id")$
get_resource_group("rgname")$
get_storage_account("mystorage")
stor$ get_blob_endpoint()

# creating an endpoint standalone
blob_endpoint("https://mystorage.blob.core.windows.net/", key="access_key")

# using an OAuth token for authentication -- note resource is 'storage.azure.com'
token <- AzureAuth::get_azure_token("https://storage.azure.com",
"myaadtenant", "app_id", "password")
storage_save_rds

Save and load R objects to/from a storage account

Description

Save and load R objects to/from a storage account

Usage

storage_save_rds(object, container, file, ...)

storage_load_rds(container, file, ...)

storage_save_rdata(..., container, file, envir = parent.frame())

storage_load_rdata(container, file, envir = parent.frame(), ...)

Arguments

<table>
<thead>
<tr>
<th>object</th>
<th>An R object to save to storage.</th>
</tr>
</thead>
<tbody>
<tr>
<td>container</td>
<td>An Azure storage container object.</td>
</tr>
<tr>
<td>file</td>
<td>The name of a file in storage.</td>
</tr>
<tr>
<td>...</td>
<td>Further arguments passed to serialize, unserialize, save and load as appropriate.</td>
</tr>
<tr>
<td>envir</td>
<td>For storage_save_rdata and storage_load_rdata, the environment from which to get objects to save, or in which to restore objects, respectively.</td>
</tr>
</tbody>
</table>
Details

These are equivalents to saveRDS, readRDS, save and load for saving and loading R objects to a storage account. With the exception of storage_save_rdata, they work via connections and so do not create temporary files. storage_save_rdata uses a temporary file so that compression of the resulting image is enabled.

See Also

storage_download, download_blob, download_azure_file, download_adls_file, save, load, saveRDS

Examples

```r
## Not run:
bl <- storage_endpoint("https://mystorage.blob.core.windows.net/", key="access_key")
cont <- storage_container(bl, "mycontainer")

storage_save_rds(iris, cont, "iris.rds")
irisnew <- storage_load_rds(iris, "iris.rds")
identical(iris, irisnew) # TRUE

storage_save_rdata(iris, mtcars, container=cont, file="dataframes.rdata")
storage_load_rdata(cont, "dataframes.rdata")

## End(Not run)
```

---

storage_write_delim  Read and write a data frame to/from a storage account

Description

Read and write a data frame to/from a storage account

Usage

```r
storage_write_delim(object, container, file, delim = "\t", ...)
storage_write_csv(object, container, file, ...)
storage_write_csv2(object, container, file, ...)
storage_read_delim(container, file, delim = "\t", ...)
storage_read_csv(container, file, ...)
storage_read_csv2(container, file, ...)
```
storage_write_delim

Arguments

- **object**: A data frame to write to storage.
- **container**: An Azure storage container object.
- **file**: The name of a file in storage.
- **delim**: For `storage_write_delim` and `storage_read_delim`, the field delimiter. Defaults to `\t` (tab).
- **...**: Optional arguments passed to the file reading/writing functions. See 'Details'.

Details

These functions let you read and write data frames to storage. `storage_read_delim` and `write_delim` are for reading and writing arbitrary delimited files. `storage_read_csv` and `write_csv` are for comma-delimited (CSV) files. `storage_read_csv2` and `write_csv2` are for files with the semicolon `;` as delimiter and comma `,` as the decimal point, as used in some European countries.

If the `readr` package is installed, they call down to `read_delim`, `write_delim`, `read_csv2` and `write_csv2`. Otherwise, they use `read_delim` and `write.table`.

See Also

`storage_download`, `download_blob`, `download_azure_file`, `download_adls_file`, `write.table`, `read.csv`, `readr::write_delim`, `readr::read_delim`

Examples

```r
## Not run:
bl <- storage_endpoint("https://mystorage.blob.core.windows.net/", key="access_key")
cont <- storage_container(bl, "mycontainer")

storage_write_csv(iris, cont, "iris.csv")
# if readr is not installed
irisnew <- storage_read_csv(cont, "iris.csv", stringsAsFactors=TRUE)
# if readr is installed
irisnew <- storage_read_csv(cont, "iris.csv", col_types="n|n|n|f")

all(mapply(identical, iris, irisnew))  # TRUE

## End(Not run)
