Type Package

Title Solution Paths for Linear and Logistic Regression Models with Categorical Predictors, with SCOPE Penalty

Version 2.0.3

Date 2021-06-08

Description Computes solutions for linear and logistic regression models with potentially high-dimensional categorical predictors. This is done by applying a nonconvex penalty (SCOPE) and computing solutions in an efficient path-wise fashion. The scaling of the solution paths is selected automatically. Includes functionality for selecting tuning parameter lambda by k-fold cross-validation and early termination based on information criteria. Solutions are computed by cyclical block-coordinate descent, iterating an innovative dynamic programming algorithm to compute exact solutions for each block.

create a design matrix of categorical variables with correlated columns.

Description

Function for use in simulations. Created design matrix of categorical variables with correlated columns.

Usage

CorrelatedDesignMatrix(n, cov_mat, c)

Arguments

- n: Number of observations
- cov_mat: p x p covariance matrix. Controls correlations of pairs of marginally U[0,1] random variables that are subsequently binned to assign categories for each variable
- c: Number of categories within each variable

Value

A data frame of categorical (factor) variables.

Examples

# Generate matrix of marginal U[0,1] variables, 0.5 pairwise correlation, that are discretised into factor variables
cov_mat = 0.5 * diag(10) + 0.5 * matrix(1, 10, 10)
x = CorrelatedDesignMatrix(100, cov_mat, 8)

Computes SCOPE predictions.

Description

Computes SCOPE predictions on new data.

Usage

## S3 method for class 'scope'
predict(object, newdata, include_intercept = TRUE, ...)

**predict.scope.logistic**

Arguments

- **object**: SCOPE model as outputted by `scope`. Must have `simply.the.best = TRUE`
- **newdata**: New covariates on which to make predictions. Must be of the same form as the model was trained on
- **include_intercept**: If TRUE, a column of 1s will be added to the (continuous) design matrix. Must match format of training data.
- **...**: Additional arguments to pass to other `predict` methods

Value

Returns n-length vector of predictions

See Also

- `scope`

---

**predict.scope.logistic**

*Computes SCOPE logistic predictions*

Description

Computes SCOPE logistic predictions on new data

Usage

```r
## S3 method for class 'scope.logistic'
predict(object, newdata, probs = TRUE, include_intercept = TRUE, ...)
```

Arguments

- **object**: SCOPE model as outputted by `scope.logistic`. Must have `simply.the.best = TRUE`
- **newdata**: New covariates on which to make predictions. Must be of the same form as the model was trained on
- **probs**: If TRUE returns probabilities, if FALSE returns binary predictions
- **include_intercept**: If TRUE, a column of 1s will be added to the (continuous) design matrix. Must match format of training data.
- **...**: Additional arguments to pass to other `predict` methods

Value

Returns n-length vector of predictions
See Also

* scope.logistic

---

**scope**  
*Compute solution for SCOPE linear models.*

**Description**

Computes solution for SCOPE linear models. Performs K-fold cross-validation for regularisation parameter lambda and can incorporate both linear and categorical (including logical) variables.

**Usage**

```r
scope(
  x,
  y,
  gamma = 8,
  lambda = NULL,
  nlambda = 100,
  lambda_min_ratio = 0.01,
  nfolds = 5,
  include_intercept = TRUE,
  return_full_beta = FALSE,
  max_iter = 1000,
  early_stopping = ifelse(pshrink > 1, TRUE, FALSE),
  early_stopping_rounds = 20,
  early_stopping_criterion = "AIC",
  noise_variance = NULL,
  terminate_eps = 1e-07,
  silent = TRUE,
  only_cross_validate = FALSE,
  grid_safe = 10,
  block_order = NULL,
  fold_assignment = NULL
)
```

**Arguments**

- **x**  
  Data frame of covariates: Can include a mix of continuous and categorical variables (no scaling of continuous covariates is performed within the program). By default an intercept will be added to the linear part; see include_intercept

- **y**  
  Response vector of length n

- **gamma**  
  Concavity parameter in MCP; see Zhang (2010)

- **lambda**  
  If NULL default sequence will be generated. Matrix of values (p_categorical times nlambda) of penalty parameter lambda. Must be non-negative and each row decreasing. Note that if lambda = 0 then no shrinkage will occur.
<table>
<thead>

</tr>
<tr>
<td>only_cross_validate</td>
<td>If TRUE then cross-validation scores for each value of lambda will be returned, but not the estimates themselves</td>
</tr>
<tr>
<td>grid_safe</td>
<td>As the automatically generated sequence of lambda values is adjusted during the first fold but fixed thereafter. For subsequent folds, this sets computation to begin at a larger value of lambda to ensure that the first solution along the path is zero so as to maintain the advantages of the pathwise approach. This specifies how many larger values of lambda should be used</td>
</tr>
<tr>
<td>block_order</td>
<td>By default the order in block coordinate descent is randomly sampled. Alternatively a permutation vector can be included here</td>
</tr>
<tr>
<td>fold_assignment</td>
<td>By default the assignments for cross-validation are randomly sampled automatically. Alternatively assignments can be included here</td>
</tr>
</tbody>
</table>

**Value**

A list of objects. Some may not be returned depending on value of arguments K, simply.cross.validated, return.full.beta.
scope.logistic

Computes solution for SCOPE logistic models

Description

Computes solution for SCOPE logistic models, computing along a path and iterating local quadratic approximations at each point. Performs K-fold cross-validation for regularisation parameter lambda and can incorporate both linear and categorical (including logical) variables. This function uses a Proximal Newton algorithm and is not guaranteed to converge. It is recommended for developer use only.

References

Examples

```R
set.seed(1)
x = UniformDesignMatrix(100, 5, 8)
y = (as.integer(x[, 1]) < 5) + (as.integer(x[, 2]) < 5) + rnorm(100)
scope_mod = scope(x, y)
x_new = UniformDesignMatrix(10, 5, 8)
predict(scope_mod, x_new)
```

- **lambda** - A matrix of the values of lambda used to compute the solution path. Columns correspond to different points on the path, rows correspond to the categorical variables. Lambda is scaled depending on the number of categories present in the data.
- **cverrors** - Provided nfolds > 1 then the cross-validation error for each point on the grid will be returned.
- **beta.full** - Contains full solution path. If nfolds > 1 then will only be returned if simply.cross.validated = FALSE and return.full.beta = TRUE. First object [[ 1 ]] is coefficients of continuous variables, [[ 2 ]] is a list of coefficients for categorical variables.
- **beta.best** - Contains solution at CV-optimal point. Requires nfolds > 1 to be returned. This must not be NULL in order to use predict.scope. First object [[ 1 ]] is coefficients of continuous variables, [[ 2 ]] is a list of coefficients for categorical variables.
- **fold.assign** - Contains fold assignments for cross-validation.
Usage

scope.logistic(
    x,
    y,
    gamma = 8,
    lambda = NULL,
    nlambda = 100,
    lambda_min_ratio = 0.01,
    nfolds = 5,
    include_intercept = TRUE,
    return_full_beta = FALSE,
    max_iter = 1000,
    max_out_iter = 1000,
    early_stopping = ifelse(pshrink > 1, TRUE, FALSE),
    early_stopping_rounds = 20,
    early_stopping_criterion = "AIC",
    noise_variance = NULL,
    terminate_eps = 1e-07,
    silent = TRUE,
    only_cross_validate = FALSE,
    grid_safe = 10,
    block_order = NULL,
    fold_assignment = NULL,
    zero_penalty = FALSE
)

Arguments

x
Data frame of covariates: Can include a mix of continuous and categorical variables (no scaling of continuous covariates is performed within the program). By default an intercept will be added to the linear part; see include_intercept

y
Response vector of length n

gamma
Concavity parameter in MCP; see Zhang (2010)

lambda
If NULL default sequence will be generated. Matrix of values (p_categorical times nlambda) of penalty parameter lambda. Must be non-negative and each row decreasing. Note that if lambda = 0 then no shrinkage will occur.

nlambda
Length of default sequence of lambda values generated if lambda = NULL

lambda_min_ratio
Ratio of largest to smallest value on default sequence of lambda values

nfolds
Number of folds in cross-validation. If nfolds = 1, no cross-validation is performed

include_intercept
If TRUE, a column of 1s will be added to the (continuous) design matrix

return_full_beta
If TRUE with cross-validation, the entire solution path will be returned instead of just the optimal point
max_iter Maximum number of iterations at each local quadratic approximation
max_out_iter Maximum number of local quadratic approximations at each value of lambda
early_stopping Early stopping based on information criterion. By default is TRUE if there are more than 1 categorical variables
early_stopping_rounds Number of iterations that information criterion must have not decreased for to terminate
early_stopping_criterion If "AIC", Akaike Information Criterion is used for early stopping. Otherwise if a positive number is given, modified Bayes Information Criterion is used with this integer as the parameter (Wang et al., 2009)
noise_variance If noise variance is known, this will be used for scaling the default values of lambda. Otherwise this will be scaled automatically
terminate_eps Epsilon for convergence criterion, is multiplied by null deviance to get terminate criterion for objective value
silent If FALSE then progress updates will be printed as solutions are computed. Useful for tuning and diagnosing convergence issues.
only_cross_validate If TRUE then cross-validation scores for each value of lambda will be returned, but not the estimates themselves
grid_safe As the automatically generated sequence of lambda values is adjusted during the first fold but fixed thereafter. For subsequent folds, this sets computation to begin at a larger value of lambda to ensure that the first solution along the path is zero so as to maintain the advantages of the pathwise approach. This specifies how many larger values of lambda should be used
block_order By default the order in block coordinate descent is randomly sampled. Alternatively a permutation vector can be included here
fold_assignment By default the assignments for cross-validation are randomly sampled automatically. Alternatively assignments can be included here
zero_penalty Fits unpenalised logistic regression model. Used for testing purposes only.

Value
A list of objects. Some may not be returned depending on value of arguments K, simply.cross.validated, return.full.beta.

- lambda - A matrix of the values of lambda used to compute the solution path. Columns correspond to different points on the path, rows correspond to the categorical variables. Lambda is scaled depending on the number of categories present in the data.
- cerrors - Provided nfolds > 1 then the cross-validation error for each point on the grid will be returned
- beta.full - Contains full solution path. If nfolds > 1 then will only be returned if simply.cross.validated = FALSE and return.full.beta = TRUE. First object [[ 1 ]] is coefficients of continuous variables, [[ 2 ]] is a list of coefficients for categorical variables
• beta.best - Contains solution at CV-optimal point. Requires nfolds > 1 to be returned. This must not be NULL in order to use predict.scope. First object [[ 1 ]] is coefficients of continuous variables, [[ 2 ]] is a list of coefficients for categorical variables
• fold.assign - Contains fold assignments for cross-validation

Examples
```r
## Not run:
x = UniformDesignMatrix(200, 5, 5)
y = (as.integer(x[, 1]) < 3) + rnorm(200)
y = as.integer(y > 0.8)
scope_mod = scope.logistic(x, y)
x_new = UniformDesignMatrix(10, 5, 5)
predict(scope_mod, x_new)
## End(Not run)
```

---

**UniformDesignMatrix**

Create a design matrix of categorical variables.

Description
Function for use in simulations, creating design matrix of categorical variables where each column is uniformly randomly distributed and independent.

Usage
```
UniformDesignMatrix(n, p, c)
```

Arguments
- `n` Number of observations
- `p` Number of variables
- `c` Number of categories within each variable

Value
A data frame of categorical (factor) variables.
Examples

x = UniformDesignMatrix(100, 10, 8)
