Package ‘ETLUtils’
August 3, 2020

Maintainer Jan Wijffels <jwijffels@bnosac.be>
License GPL-2
Title Utility Functions to Execute Standard Extract/Transform/Load
  Operations (using Package ‘ff’) on Large Data
Type Package
LazyLoad yes
Author Jan Wijffels
Description Provides functions to facilitate the use of the ‘ff’ package
  in interaction with big data in ‘SQL’ databases (e.g. in ‘Oracle’, ‘MySQL’,
  ‘PostgreSQL’, ‘Hive’) by allowing easy importing directly into ‘ffdf’ objects
  using ‘DBI’, ‘RODBC’ and ‘RJDBC’. Also contains some basic utility functions to
  do fast left outer join merging based on ‘match’, factorisation of data and a
  basic function for re-coding vectors.
Version 1.5
URL https://github.com/jwijffels/ETLUtils
Depends ff (>= 4.0.0)
Imports bit (>= 4.0.0)
Suggests RSQLite, zoo, DBI, RODBC, RJDBC
RoxygenNote 7.1.0
NeedsCompilation no
Repository CRAN
Date/Publication 2020-08-03 09:42:08 UTC

**factorise**

---

**ETLUtils-package**

*Extra utility functions to execute standard ETL operations on large data*

**Description**

Provides functions to load big data (e.g. from Oracle) directly into `ffdf` objects using DBI and some utility functions like recoding and matchmerge which does fast left outer join merging based on match.

**Author(s)**

Jan Wijffels <jwijffels@bnosac.be>

**Examples**

```r
# See the specified functions in the package
```

---

**factorise**

*Put character vectors, columns of a data.frame or list elements as factor*

**Description**

Put character vectors, columns of a data.frame or list elements as factor if they are character strings or optionally if they are logicals

**Usage**

```r
factorise(x, logicals = FALSE, ...)
```

### Default S3 method:

```r
factorise(x, logicals = FALSE, ...)
```

### S3 method for class 'character'

```r
factorise(x, logicals = FALSE, ...)
```
## S3 method for class 'data.frame'
factorise(x, logicals = FALSE, ...)

## S3 method for class 'list'
factorise(x, logicals = FALSE, ...)

**Arguments**

- **x**
  a character vector, a data.frame or a list

- **logicals**
  logical indicating if logical vectors should also be converted to factors. Defaults to FALSE.

- **...**
  optional arguments passed on to the methods

**Value**

The updated x vector/data.frame or list where the character vectors or optionally logical elements are converted to factors

**See Also**

`as.factor`, `factor`

**Examples**

```r
x <- data.frame(x = 1:4, y = LETTERS[1:4], b = c(TRUE, FALSE, NA, TRUE), stringsAsFactors=FALSE)
str(factorise(x))
str(factorise(x, logicals = TRUE))
str(factorise(list(a = LETTERS, b = 1:10, c = pi, d = list(x = x))))
```

---

**matchmerge**

Merge two data frames (fast) by common columns by performing a left (outer) join or an inner join.

**Description**

Merge two data frames (fast) by common columns by performing a left (outer) join or an inner join. The data frames are merged on the columns given by by.x and by.y. Columns can be specified only by name. This differs from the merge function from the base package in that merging is done based on 1 column key only. If more than one column is supplied in by.x and by.y, these columns will be concatenated together to form 1 key which will be used to match. Alternatively, by.x and by.y can be 2 vectors of length NROW(x) which will be used as keys.
matchmerge

matchmerge(
  x,
  y,
  by.x,
  by.y,
  all.x = FALSE,
  by.iskey = FALSE,
  suffix = ".y",
  add.columns = colnames(y),
  check.duplicates = TRUE,
  trace = FALSE
)

Arguments

x the left hand side data frame to merge
y the right hand side data frame to merge
or a vector in which case you always need to supply by.y as a vector, make sure
by.iskey is set to TRUE and provide in add.columns the column name for which
y will be relabelled to in the joined data frame (see the example).
by.x either the name of 1 column in x or a character vector of length NROW(x) which
will be used as key to merge the 2 data frames
by.y either the name of 1 column in y or a character vector of length NROW(x) which
will be used as key to merge the 2 data frames. Duplicate values in by.y are not
allowed.
all.x logical, if TRUE, then extra rows will be added to the output, one for each row
in x that has no matching row in y. These rows will have NAs in those columns
that are usually filled with values from y. The default is FALSE, so that only
rows with data from both x and y are included in the output. The default value
corresponds to an inner join. If TRUE is supplied, this corresponds to a left
(outer) join.
by.iskey Logical, indicating that the by.x and the by.y inputs are vectors of length NROW(x)
and NROW(y) instead of column names in x and y. If this is FALSE, the input
columns will be pasted together to create a key to merge upon. Otherwise, the
function will use the by.x and by.y vectors directly as matching key. Defaults to
FALSE indicating the by.x and by.y are column names in x and y.
suffix a character string to be used for duplicate column names in x and y to make the
y columns unique.
add.columns character vector of column names in y to merge to the x data frame. Defaults to
all columns in y.
check.duplicates checks if by.y contains duplicates which is not allowed. Defaults to TRUE.
trace logical, indicating to print some informative messages about the progress
**matchmerge**

**Details**

The rows in the right hand side data frame that match on the specific key are extracted, and joined together with the left hand side data frame.

Merging is done based on the match function on the key value. This makes the function a lot faster when compared to applying merge, especially for large data frames (see the example). And also the memory consumption is a lot smaller.

In SQL database terminology, the default value of all.x = FALSE gives a natural join, a special case of an inner join. Specifying all.x = FALSE gives a left (outer) join. Right (outer) join or (full) outer join are not provided in this function.

**Value**

data frame with x joined with y based on the supplied columns. The output columns are the columns in x followed by the extra columns in y.

**See Also**

cbind, match, merge

**Examples**

```r
left <- data.frame(idlhs = c(1:4, 3:5), a = LETTERS[1:7], stringsAsFactors = FALSE)
right <- data.frame(idrhs = c(1:4), b = LETTERS[8:11], stringsAsFactors = FALSE)
## Inner join
matchmerge(x=left, y=right, by.x = "idlhs", by.y = "idrhs")

## Left outer join in 2 ways
matchmerge(x=left, y=right, by.x = "idlhs", by.y = "idrhs", all.x=TRUE)
matchmerge(x=left, y=right, by.x = left$idlhs, by.y = right$idrhs, all.x=TRUE, by.iskey=TRUE)

## Show usage when y is just a vector instead of a data.frame
matchmerge(x=left, y=right$b, by.x = left$idlhs, by.y = right$idrhs, all.x=TRUE, by.iskey=TRUE, add.columns="b.renamed")

## Show speedup difference with merge
## Not run:
size <- 100000
dimension <- seq(Sys.Date(), Sys.Date()+10, by = "day")
left <- data.frame(date = rep(dimension, size), sales = rnorm(size))
right <- data.frame(date = dimension, feature = dimension-7, feature = dimension-14)
dim(left)
dim(right)
print(system.time(merge(left, right, by.x="date", by.y="date", all.x=TRUE, all.y=FALSE)))
print(system.time(matchmerge(left, right, by.x="date", by.y="date", all.x=TRUE, by.iskey=FALSE)))
## End(Not run)
## Show example usage
products <- expand.grid(product = c("Pepsi", "Coca Cola"), type = c("Can","Bottle"),
```
size = c("6Ml","8Ml"), distributor = c("Distri X","Distri Y"), salesperson = c("Mr X","Mr Y"), stringsAsFactors=FALSE)
products <- products[!duplicated(products[, c("product","type","size")]), ]
products$key <- paste(products$product, products$type, products$size, sep=".")
sales <- expand.grid(item = unique(products$key), sales = rnorm(10000, mean = 100))
str(products)
str(sales)
info <- matchmerge(x=sales, y=products,
  by.x=sales$item, by.y=products$key, all.x=TRUE, by.iskey=TRUE,
  add.columns=c("size","distributor"), check.duplicates=FALSE)
str(info)
tapply(info$sales, info@distributor, FUN=sum)

naLOCFPlusone

Performs NA replacement by last observation carried forward but adds 1 to the last observation carried forward.

Description

Performs NA replacement by last observation carried forward but adds 1 to the last observation carried forward.

Usage

naLOCFPlusone(x)

Arguments

x a numeric vector

Value

a vector where NA's are replaced with the LOCF + 1

See Also

na.locf

Examples

require(zoo)
x <- c(2,NA,NA,4,5,2,NA)
nanoLOCFPlusone(x)
Read data from a DBI connection into an \textit{ffdf}. This can for example be used to import large datasets from Oracle, SQLite, MySQL, PostgreSQL, Hive or other SQL databases into R.

### Usage

```r
code
```

### Arguments

- **query**: the SQL query to execute on the DBI connection
- **dbConnect.args**: a list of arguments to pass to DBI’s \textit{dbConnect} (like \texttt{drv}, \texttt{dbname}, \texttt{username}, \texttt{password}). See the examples.
- **dbSendQuery.args**: a list containing database-specific parameters which will be passed to \textit{dbSendQuery}. Defaults to an empty list.
- **dbFetch.args**: a list containing optional database-specific parameters which will be passed to \textit{dbFetch}. Defaults to an empty list.
- **x**: NULL or an optional \textit{ffdf} object to which the read records are appended. See documentation in \textit{read.table.ffd} for more details and the example below.
- **nrows**: Number of rows to read from the query resultset. Default value of -1 reads in all rows.
- **first.rows**: chunk size (rows) to read for first chunk from the query resultset.
next.rows  chunk size (rows) to read sequentially for subsequent chunks from the query resultset. Currently, this must be specified.

levels  optional specification of factor levels. A list with as names the names the columns of the data.frame fetched in the first.rows, containing levels of the factors.

appendLevels  logical. A vector of permissions to expand levels for factor columns. See documentation in read.table.ffdf for more details.

asffdf_args  further arguments passed to as.ffdf (ignored if ‘x’ gives an ffdf object)

BATCHBYTES  integer: bytes allowed for the size of the data.frame storing the result of reading one chunk. See documentation in read.table.ffdf for more details.

VERBOSE  logical: TRUE to verbose timings for each processed chunk (default FALSE).

colClasses  See documentation in read.table.ffdf

transFUN  function applied to the data frame after each chunk is retrieved by dbFetch

...  optional parameters passed on to transFUN

Details

Opens up the DBI connection using DBI::dbConnect, sends the query using DBI::dbSendQuery and DBI::dbFetch-es the results in batches of next.rows rows. Heavily borrowed from read.table.ffdf

Value

An ffdf object unless the query returns zero records in which case the function will return the data.frame returned by dbFetch and possibly transFUN.

See Also

read.table.ffdf, read.odbc.ffdf

Examples

require(ff)

##
## Example query using data in sqlite
##
require(RSQLite)
dbfile <- system.file("smalldb.sqlite3", package="ETLUtils")
drv <- dbDriver("SQLite")
query <- "select * from testdata limit 10000"
x <- read.dbi.ffdf(query = query, dbConnect.args = list(drv = drv, dbname = dbfile), first.rows = 100, next.rows = 1000, VERBOSE=TRUE)
class(x)
x[1:10, ]

## show it is the same as getting the data directly using RSQLite
## apart from characters which are factors in ffdf objects
directly <- dbGetQuery(dbConnect(drv = drv, dbname = dbfile), query)
directly <- as.data.frame(as.list(directly), stringsAsFactors=TRUE)
all.equal(x[,], directly)

## show how to use the transFUN argument to transform the data before saving into the ffdf
## and shows the use of the levels argument
query <- "select * from testdata limit 10"
x <- read.dbi.ffdf(query = query, dbConnect.args = list(drv = drv, dbname = dbfile),
    first.rows = 100, next.rows = 1000, VERBOSE=TRUE, levels = list(a = rev(LETTERS)),
    transFUN = function(x, subtractdays){
        x$b <- as.Date(x$b)
x$b.subtractdaysago <- x$b - subtractdays
    x
    }, subtractdays=7)
class(x)
x[1:10,]
## remark that the levels of column a are reversed due to specifying the levels argument correctly
levels(x$a)

## show how to append data to an existing ffdf object
transformexample <- function(x, subtractdays){
    x$b <- as.Date(x$b)
x$b.subtractdaysago <- x$b - subtractdays
    x
}
dim(x)
x[,]combined <- read.dbi.ffdf(query = query,
    dbConnect.args = list(drv = drv, dbname = dbfile),
    first.rows = 100, next.rows = 1000, x = x, VERBOSE=TRUE,
    transFUN = transformexample, subtractdays=1000)
dim(combined)
combined[,]## Example query using ROracle. Do try this at home with some larger data :)
## Not run:
require(ROracle)
query <- "select OWNER, TABLE_NAME, TABLESPACE_NAME, NUM_ROWS, LAST_ANALYZED from all_all_tables"
x <- read.dbi.ffdf(query=query, dbConnect.args = list(drv =/dbDriver("Oracle"),
    user = "YourUser", password = "YourPassword", dbname = "Mydatabase"),
    first.rows = 100, next.rows = 50000, nrows = -1, VERBOSE=TRUE)
## End(Not run)

**read.jdbc.ffdf**  
*Read data from a JDBC connection into an ffdf.*
Description

Read data from a JDBC connection into an ffdf. This can for example be used to import large datasets from Oracle, SQLite, MySQL, PostgreSQL, Hive or other SQL databases into R.

Usage

read.jdbc.ffdf(
  query = NULL,
  dbConnect.args = list(drv = NULL, dbname = NULL, username = "", password = ""),
  dbSendQuery.args = list(),
  dbFetch.args = list(),
  x = NULL,
  nrows = -1,
  first.rows = NULL,
  next.rows = NULL,
  levels = NULL,
  appendLevels = TRUE,
  asffdf_args = list(),
  BATCHBYTES = getOption("ffbatchbytes"),
  VERBOSE = FALSE,
  colClasses = NULL,
  transFUN = NULL,
  ...
)

Arguments

query the SQL query to execute on the JDBC connection

dbConnect.args a list of arguments to pass to JDBC’s RJDBC::dbConnect (like drv, dbname, username, password). See the examples.

dbSendQuery.args a list containing database-specific parameters which will be passed to RJDBC::dbSendQuery. Defaults to an empty list.

dbFetch.args a list containing optional database-specific parameters which will be passed to RJDBC::dbFetch. Defaults to an empty list.

x NULL or an optional ffdf object to which the read records are appended. See documentation in read.table.ffdf for more details and the example below.

nrows Number of rows to read from the query resultset. Default value of -1 reads in all rows.

first.rows chunk size (rows) to read for first chunk from the query resultset

next.rows chunk size (rows) to read sequentially for subsequent chunks from the query resultset. Currently, this must be specified.

levels optional specification of factor levels. A list with as names the names the columns of the data.frame fetched in the first.rows, containing levels of the factors.
appendLevels  logical. A vector of permissions to expand levels for factor columns. See documentation in \texttt{read.table.ffdf} for more details.

asffdf_args  further arguments passed to \texttt{as.ffdf} (ignored if 'x' gives an ffdf object)

BATCHBYTES  integer: bytes allowed for the size of the data.frame storing the result of reading one chunk. See documentation in \texttt{read.table.ffdf} for more details.

VERBOSE  logical: TRUE to verbose timings for each processed chunk (default FALSE).

colClasses  See documentation in \texttt{read.table.ffdf}

transFUN  function applied to the data frame after each chunk is retrieved by \texttt{RJDBC::dbFetch}

...  optional parameters passed on to transFUN

Details

Opens up the JDBC connection using \texttt{RJDBC::dbConnect}, sends the query using \texttt{RJDBC::dbSendQuery} and \texttt{RJDBC::dbFetch}-es the results in batches of next.rows rows. Heavily borrowed from \texttt{read.table.ffdf}

Value

An ffdf object unless the query returns zero records in which case the function will return the data.frame returned by \texttt{RJDBC::dbFetch} and possibly transFUN.

See Also

\texttt{read.table.ffdf, read.jdbc.ffdf}

Examples

```r
## Not run:
require(ff)

##
## Example query using data in sqlite
##
require(RSQLite)

dbfile <- system.file("smalldb.sqlite3", package="ETLUtils")
drv <- JDBC(drivers = "org.sqlite.JDBC", classPath = "/usr/local/lib/sqlite-jdbc-3.7.2.jar")
query <- "select * from testdata limit 10000"
x <- read.jdbc.ffdf(query = query,
                    dbConnect.args = list(drv = drv, url = sprintf("jdbc:sqlite:%s", dbfile)),
                    first.rows = 100, next.rows = 1000, VERBOSE=TRUE)
class(x)
x[1:10, ]

## End(Not run)
```
read.odbc.ffdf

Read data from a ODBC connection into an ffdf.

Description

Read data from a ODBC connection into an ffdf. This can for example be used to import large datasets from Oracle, SQLite, MySQL, PostgreSQL, Hive or other SQL databases into R.

Usage

read.odbc.ffdf(
  query = NULL,
  odbcConnect.args = list(dsn = NULL, uid = "", pwd = ""),
  odbcDriverConnect.args = list(connection = ""),
  odbcQuery.args = list(),
  sqlGetResults.args = list(),
  x = NULL,
  nrows = -1,
  first.rows = NULL,
  next.rows = NULL,
  levels = NULL,
  appendLevels = TRUE,
  asffdf_args = list(),
  BATCHBYTES = getOption("ffbatchbytes"),
  VERBOSE = FALSE,
  colClasses = NULL,
  transFUN = NULL,
  ...
)

Arguments

query the SQL query to execute on the ODBC connection

odbcConnect.args

a list of arguments to pass to ODBC’s odbcConnect (like dsn, uid, pwd). See the examples.

odbcDriverConnect.args

a list of arguments to pass to ODBC’s odbcDriverConnect (like connection). If you want to connect using odbcDriverConnect instead of odbcConnect.

odbcQuery.args a list of arguments to pass to ODBC’s odbcQuery, like rows_at_time. Defaults to an empty list.

sqlGetResults.args

a list containing optional parameters which will be passed to sqlGetResults. Defaults to an empty list. The max parameter will be overwritten with first.rows and next.rows when importing in batches.
read.odbc.ffdf

x

NULL or an optional ffdf object to which the read records are appended. See documentation in `read.table.ffdf` for more details and the example below.
nrows

Number of rows to read from the query resultset. Default value of -1 reads in all rows.
first.rows

chunk size (rows) to read for first chunk from the query resultset
next.rows

chunk size (rows) to read sequentially for subsequent chunks from the query resultset. Currently, this must be specified.
levels

optional specification of factor levels. A list with as names the names the columns of the data.frame fetched in the first.rows, containing levels of the factors.
appendLevels

logical. A vector of permissions to expand levels for factor columns. See documentation in `read.table.ffdf` for more details.
asffdf_args

further arguments passed to `as.ffdf` (ignored if 'x' gives an ffdf object)
BATCHBYTES

integer: bytes allowed for the size of the data.frame storing the result of reading one chunk. See documentation in `read.table.ffdf` for more details.
VERBIOSE

logical: TRUE to verbose timings for each processed chunk (default FALSE).
colClasses

See documentation in `read.table.ffdf`
transFUN

function applied to the data frame after each chunk is retrieved by `sqlGetResults`
...

optional parameters passed on to transFUN

Details

Opens up the ODBC connection using `RODBC::odbcConnect` or `RODBC::odbcDriverConnect`, sends the query using `RODBC::odbcQuery` and retrieves the results in batches of next.rows rows using `RODBC::sqlGetResults`. Heavily borrowed from `read.table.ffdf`

Value

An ffdf object unless the query returns zero records in which case the function will return the data.frame returned by `sqlGetResults` and possibly transFUN.

See Also

`read.table.ffdf`, `read.dbi.ffdf`

Examples

```r
## Using the sqlite database (smalldb.sqlite3) in the /inst folder of the package
## set up the sqlite ODBC driver (www.stats.ox.ac.uk/pub/bdr/RODBC-manual.pdf)
## and call it 'smalltestsqldb'
## Not run:
require(RODBC)
x <- read.odbc.ffdf(
query = "select * from testdata limit 10000",
odbcConnect.args = list(
```
recoder

Recodes the values of a character vector

Description

Recodes the values of a character vector

Usage

recoder(x, from = c(), to = c())

Arguments

x character vector

from character vector with old values

to character vector with new values

Value

x where from values are recoded to the supplied to values

See Also

match

Examples

recoder(x=append(LETTERS, NA, 5), from = c("A","B"), to = c("a.123","b.123"))
renameColumns

Renames variables in a data frame.

Description

Renames variables in a data frame.

Usage

renameColumns(x, from = "", to = "")

Arguments

x data frame to be modified.
from character vector containing the current names of each variable to be renamed.
to character vector containing the new names of each variable to be renamed.

Value

The updated data frame x where the variables listed in from are renamed to the corresponding to column names.

See Also

colnames, recoder

Examples

x <- data.frame(x = 1:4, y = LETTERS[1:4])
renameColumns(x, from = c("x","y"), to = c("digits","letters"))

write.dbi.ffdf

Write ffdf data to a database table by using a DBI connection.

Description

Write ffdf data to a database table by using a DBI connection. This can for example be used to store large ffdf datasets from R in Oracle, SQLite, MySQL, PostgreSQL, Hive or other SQL databases.
Mark that for very large datasets, these SQL databases might have tools to speed up by bulk loading. You might also consider that as an alternative to using this procedure.
write.dbi.ffdf

Usage

write.dbi.ffdf(
  x,  
  name,  
  dbConnect.args = list(drv = NULL, dbname = NULL, username = "", password = ""),  
  RECORDBYTES = sum(.rambytes[vmode(x)]),  
  BATCHBYTES = getOption("ffbatchbytes"),  
  by = NULL,  
  VERBOSE = FALSE,  
...  
)

Arguments

x      the ffdf to write to the database
name   character string with the name of the table to store the data in. Passed on to dbWriteTable.
dbConnect.args a list of arguments to pass to DBI's dbConnect (like drv, dbname, username, password). See the examples.
RECORDBYTES optional integer scalar representing the bytes needed to process a single row of the ffdf
BATCHBYTES integer: bytes allowed for the size of the data.frame storing the result of reading one chunk. See documentation in read.table.ffdf for more details.
by      integer passed on to chunk indicating to write to the database in chunks of this size. Overwrites the behaviour of BATCHBYTES and RECORDBYTES.
VERBOSE logical: TRUE to verbose timings for each processed chunk (default FALSE).
...     optional parameters passed on to dbWriteTable

Details

Opens up the DBI connection using DBI::dbConnect, writes data to the SQL table using DBI::dbWriteTable by extracting the data in batches from the ffdf and appending them to the table.

Value

invisible()

See Also

dbWriteTable, chunk

Examples

require(ff)

##
## Example query using data in sqlite
write.jdbc.ffdf

Write ffdf data to a database table by using a JDBC connection.

Description

Write ffdf data to a database table by using a JDBC connection. This can for example be used to store large ffdf datasets from R in Oracle, SQLite, MySQL, PostgreSQL, Hive or other SQL databases.

Mark that for very large datasets, these SQL databases might have tools to speed up by bulk loading. You might also consider that as an alternative to using this procedure.

Usage

write.jdbc.ffdf(
  x,
  name,
  dbConnect.args = list(drv = NULL, dbname = NULL, username = "", password = ""),
  RECORDBYTES = sum(.rambytes[vmode(x)]),
  BATCHBYTES =getOption("ffbatchbytes"),
  by = NULL,
)
Arguments

x the ffdf to write to the database
name character string with the name of the table to store the data in. Passed on to dbWriteTable.
dbConnect.args a list of arguments to pass to JDBC's RJDBC::dbConnect (like drv, dbname, username, password). See the examples.
RECORDBYTES optional integer scalar representing the bytes needed to process a single row of the ffdf
BATCHBYTES integer: bytes allowed for the size of the data.frame storing the result of reading one chunk. See documentation in read.table.ffdf for more details.
by integer passed on to chunk indicating to write to the database in chunks of this size. Overwrites the behaviour of BATCHBYTES and RECORDBYTES.
VERBOSE logical: TRUE to verbose timings for each processed chunk (default FALSE).

Details

Opens up the JDBC connection using RJDBC::dbConnect, writes data to the SQL table using RJDBC::dbWriteTable by extracting the data in batches from the ffdf and appending them to the table.

Value

invisible()

See Also

JDBCConnection-methods, chunk

Examples

```r
## Not run:
require(ff)

##
## Example query using data in sqlite
##
require(RJDBC)
dbfile <- system.file("smalldb.sqlite3", package="ETLUtils")
drv <- JDBC(driverClass = "org.sqlite.JDBC", classPath = "/usr/local/lib/sqlite-jdbc-3.7.2.jar")
query <- "select * from testdata limit 10000"
x <- read.jdbc.ffdf(query = query,
  dbConnect.args = list(drv = drv, url = sprintf("jdbc:sqlite:%s", dbfile)),
)```
write.odbc.ffdf

Write ffdf data to a database table by using an ODBC connection.

**Description**

Write ffdf data to a database table by using an ODBC connection. This can for example be used to store large ffdf datasets from R in Oracle, SQLite, MySQL, PostgreSQL, Hive or other SQL databases.

Mark that for very large datasets, these SQL databases might have tools to speed up by bulk loading. You might also consider that as an alternative to using this procedure.

**Usage**

```r
write.odbc.ffdf(
  x,
  tablename,
  odbcConnect.args = list(dsn = NULL, uid = "", pwd = ""),
  RECORDBYTES = sum(.rambytes[vmode(x)]),
  BATCHBYTES = getOption("ffbatchbytes"),
  by = NULL,
  VERBOSE = FALSE,
  ...)
```

**Arguments**

- `x` the ffdf to write to the database
- `tablename` character string with the name of the table to store the data in. Passed on to `sqlSave`.
- `odbcConnect.args` a list of arguments to pass to ODBC’s `odbcConnect` (like dsn, uid, pwd). See the examples.
- `RECORDBYTES` optional integer scalar representing the bytes needed to process a single row of the ffdf
- `BATCHBYTES` integer: bytes allowed for the size of the data.frame storing the result of reading one chunk. See documentation in `read.table.ffdf` for more details.
by integer passed on to chunk indicating to write to the database in chunks of this size. Overwrites the behaviour of BATCHBYTES and RECORDBYTES.

VERBOSE logical: TRUE to verbose timings for each processed chunk (default FALSE).

... optional parameters passed on to sqlSave

Details

Opens up the ODBC connection using RODBC::odbcConnect, writes data to the SQL table using RODBC::sqlSave by extracting the data in batches from the fffd and appending them to the table.

Value

invisible()

See Also

sqlSave, chunk

Examples

## Using the sqlite database (smalldb.sqlite3) in the /inst folder of the package
## set up the sqlite ODBC driver (www.stats.ox.ac.uk/pub/bdr/RODBC-manual.pdf)
## and call it ‘smalltestsqilitedb’
##
## Not run:
require(RODBC)
x <- read.odbc.ffdf(query = "select * from testdata limit 10000",
odbcConnect.args = list(dsn="smalltestsqilitedb", uid = "", pwd = "",
believeNRows = FALSE, rows_at_time = 1),
nrows = -1,
first.rows = 100, next.rows = 1000, VERBOSE = TRUE)

write.odbc.ffdf(x = x, tablename = "testdata", rownames = FALSE, append = TRUE,
odbcConnect.args = list(dsn="smalltestsqilitedb", uid = "", pwd = "",
believeNRows = FALSE, rows_at_time = 1),
by = 1000, VERBOSE=TRUE)

## End(Not run)
