

Package ‘akima’

December 20, 2016

Version 0.6-2

Date 2016-12-16

Title Interpolation of Irregularly and Regularly Spaced Data

Maintainer Albrecht Gebhardt <albrecht.gebhardt@aau.at>

Description Several cubic spline interpolation methods of H. Akima for irregular and regular gridded data are available through this package, both for the bivariate case (irregular data: ACM 761, regular data: ACM 760) and univariate case (ACM 433 and ACM 697). Linear interpolation of irregular gridded data is also covered by reusing D. J. Renkas triangulation code which is part of Akimas Fortran code. A bilinear interpolator for regular grids was also added for comparison with the bicubic interpolator on regular grids.

akima	<i>Waveform Distortion Data for Bivariate Interpolation</i>
-------	---

Description

akima is a list with components x, y and z which represents a smooth surface of z values at selected points irregularly distributed in the x-y plane.

The data was taken from a study of waveform distortion in electronic circuits, described in: Hiroshi Akima, "A Method of Bivariate Interpolation and Smooth Surface Fitting Based on Local Procedures", CACM, Vol. 17, No. 1, January 1974, pp. 18-20.

References

akima760

Sample data from Akima's Bicubic Spline Interpolation code (TOMS 760)

Description

akima760 is a list with vector components x, y and a matrix z which represents a smooth surface of z values at the points of a regular grid spanned by the vectors x and y.

References

aspline

Univariate Akima interpolation

Description

The function returns a list of points which smoothly interpolate given data points, similar to a curve drawn by hand.

Usage

```
aspline(x, y=NULL, xout, n = 50, ties = mean, method="original", degree=3)
```

Arguments

<code>x, y</code>	vectors giving the coordinates of the points to be interpolated. Alternatively a single plotting structure can be specified: see xy.coords .
<code>xout</code>	an optional set of values specifying where interpolation is to take place.
<code>n</code>	If <code>xout</code> is not specified, interpolation takes place at <code>n</code> equally spaced points spanning the interval $[\min(x), \max(x)]$.
<code>ties</code>	Handling of tied <code>x</code> values. Either a function with a single vector argument returning a single number result or the string "ordered".
<code>method</code>	either "original" method after Akima (1970) or "improved" method after Akima (1991)
<code>degree</code>	if improved algorithm is selected: degree of the polynomials for the interpolating function

Details

The original algorithm is based on a piecewise function composed of a set of polynomials, each of degree three, at most, and applicable to successive interval of the given points. In this method, the slope of the curve is determined at each given point locally, and each polynomial representing a portion of the curve between a pair of given points is determined by the coordinates of and the slopes at the points.

Value

A list with components `x` and `y`, containing `n` coordinates which interpolate the given data points.

bicubic

Bivariate Interpolation for Data on a Rectangular grid

Description

The description in the Fortran code says:

This subroutine performs interpolation of a bivariate function, $z(x,y)$, on a rectangular grid in the x - y plane. It is based on the revised Akima method.

In this subroutine, the interpolating function is a piecewise function composed of a set of bicubic (bivariate third-degree) polynomials, each applicable to a rectangle of the input grid in the x - y plane. Each polynomial is determined locally.

This subroutine has the accuracy of a bicubic polynomial, i.e., it interpolates accurately when all data points lie on a surface of a bicubic polynomial.

The grid lines can be unevenly spaced.

Usage

```
bicubic(x, y, z, x0, y0)
```

Arguments

x	a vector containing the x coordinates of the rectangular data grid.
y	a vector containing the y coordinates of the rectangular data grid.
z	a matrix containing the $z[i, j]$ data values for the grid points $(x[i], y[j])$.
x0	vector of x coordinates used to interpolate at.
y0	vector of y coordinates used to interpolate at.

Details

This function is a R interface to Akima's Rectangular-Grid-Data Fitting algorithm (TOMS 760). The algorithm has the accuracy of a bicubic (bivariate third-degree) polynomial.

Value

This function produces a list of interpolated points:

x	vector of x coordinates.
y	vector of y coordinates.
z	vector of interpolated data z.

If you need an output grid, see [bicubic.grid](#).

Note

Use [interp](#) for the general case of irregular gridded data!

# interpolate at the diagonal of the grid [0,8]x[0,10]
akima.bic <- bicubic(akima760$x, akima760$y, akima760$z,
                    seq(0,8,length=50), seq(0,10,length=50))
plot(sqrt(akima.bic$x^2+akima.bic$y^2), akima.bic$z, type="l")
```

 bicubic.grid

Bicubic Interpolation for Data on a Rectangular grid

Description

The description in the Fortran code says:

This subroutine performs interpolation of a bivariate function, $z(x,y)$, on a rectangular grid in the x - y plane. It is based on the revised Akima method.

In this subroutine, the interpolating function is a piecewise function composed of a set of bicubic (bivariate third-degree) polynomials, each applicable to a rectangle of the input grid in the x - y plane. Each polynomial is determined locally.

This subroutine has the accuracy of a bicubic polynomial, i.e., it interpolates accurately when all data points lie on a surface of a bicubic polynomial.

The grid lines can be unevenly spaced.

Usage

```
bicubic.grid(x,y,z,xlim=c(min(x),max(x)),ylim=c(min(y),max(y)),
            nx=40,ny=40,dx=NULL,dy=NULL)
```

Arguments

<code>x</code>	a vector containing the x coordinates of the rectangular data grid.
<code>y</code>	a vector containing the y coordinates of the rectangular data grid.
<code>z</code>	a matrix containing the $z[i,j]$ data values for the grid points $(x[i],y[j])$.
<code>xlim</code>	vector of length 2 giving lower and upper limit for range x coordinates used for output grid.
<code>ylim</code>	vector of length 2 giving lower and upper limit for range of y coordinates used for output grid.
<code>nx</code>	output grid dimension in x direction.
<code>ny</code>	output grid dimension in y direction.
<code>dx</code>	output grid spacing in x direction, not used by default, overrides <code>nx</code> if specified.
<code>dy</code>	output grid spacing in y direction, not used by default, overrides <code>ny</code> if specified..

Details

This function is a R interface to Akima's Rectangular-Grid-Data Fitting algorithm (TOMS 760). The algorithm has the accuracy of a bicubic (bivariate third-degree) polynomial.

Value

This function produces a grid of interpolated points, feasible to be used directly with [image](#) and [contour](#):

x vector of x coordinates of the output grid.
y vector of y coordinates of the output grid.
z matrix of interpolated data for the output grid.

Note

Use [interp](#) for the general case of irregular gridded data!

contour(akima.bic, levels=breaks, add=TRUE)
```

bilinear

Bilinear Interpolation for Data on a Rectangular grid

Description

This is an implementation of a bilinear interpolating function.

For a point (x_0, y_0) contained in a rectangle $(x_1, y_1), (x_2, y_1), (x_2, y_2), (x_1, y_2)$ and $x_1 < x_2, y_1 < y_2$, the first step is to get $z()$ at locations (x_0, y_1) and (x_0, y_2) as convex linear combinations $z(x_0, y^*) = a * z(x_1, y^*) + (1 - a) * z(x_2, y^*)$ where $a = (x_2 - x_1) / (x_0 - x_1)$ for $y^* = y_1, y_2$. In a second step $z(x_0, y_0)$ is calculated as convex linear combination between $z(x_0, y_1)$ and $z(x_0, y_2)$ as $z(x_0, y_0) = b * z(x_0, y_1) + (1 - b) * z(x_0, y_2)$ where $b = (y_2 - y_1) / (y_0 - y_1)$.

Finally, $z(x_0, y_0)$ is a convex linear combination of the z values at the corners of the containing rectangle with weights according to the distance from (x_0, y_0) to these corners.

The grid lines can be unevenly spaced.

Usage

```
bilinear(x, y, z, x0, y0)
```

Arguments

x	a vector containing the x coordinates of the rectangular data grid.
y	a vector containing the y coordinates of the rectangular data grid.
z	a matrix containing the $z[i, j]$ data values for the grid points $(x[i], y[j])$.
x0	vector of x coordinates used to interpolate at.
y0	vector of y coordinates used to interpolate at.

Value

This function produces a list of interpolated points:

x	vector of x coordinates.
y	vector of y coordinates.
z	vector of interpolated data z.

If you need an output grid, see [bilinear.grid](#).

Note

Use [interpp](#) for the general case of irregular gridded data!

Examples

```
data(akima760)
# interpolate at the diagonal of the grid [0,8]x[0,10]
akima.bil <- bilinear(akima760$x, akima760$y, akima760$z,
                    seq(0, 8, length=50), seq(0, 10, length=50))
plot(sqrt(akima.bil$x^2+akima.bil$y^2), akima.bil$z, type="l")
```

Description

This is an implementation of a bilinear interpolating function.

For a point (x_0, y_0) contained in a rectangle $(x_1, y_1), (x_2, y_1), (x_2, y_2), (x_1, y_2)$ and $x_1 < x_2, y_1 < y_2$, the first step is to get $z()$ at locations (x_0, y_1) and (x_0, y_2) as convex linear combinations $z(x_0, y^*) = a * z(x_1, y^*) + (1 - a) * z(x_2, y^*)$ where $a = (x_2 - x_1) / (x_0 - x_1)$ for $y^* = y_1, y_2$. In a second step $z(x_0, y_0)$ is calculated as convex linear combination between $z(x_0, y_1)$ and $z(x_0, y_2)$ as $z(x_0, y_0) = b * z(x_0, y_1) + (1 - b) * z(x_0, y_2)$ where $b = (y_2 - y_1) / (y_0 - y_1)$.

Finally, $z(x_0, y_0)$ is a convex linear combination of the z values at the corners of the containing rectangle with weights according to the distance from (x_0, y_0) to these corners.

The grid lines can be unevenly spaced.

Usage

```
bilinear.grid(x,y,z,xlim=c(min(x),max(x)),ylim=c(min(y),max(y)),
             nx=40,ny=40,dx=NULL,dy=NULL)
```

Arguments

x	a vector containing the x coordinates of the rectangular data grid.
y	a vector containing the y coordinates of the rectangular data grid.
z	a matrix containing the $z[i, j]$ data values for the grid points $(x[i], y[j])$.
xlim	vector of length 2 giving lower and upper limit for range x coordinates used for output grid.
ylim	vector of length 2 giving lower and upper limit for range of y coordinates used for output grid.
nx	output grid dimension in x direction.
ny	output grid dimension in y direction.
dx	output grid spacing in x direction, not used by default, overrides nx if specified.
dy	output grid spacing in y direction, not used by default, overrides ny if specified..

Value

This function produces a grid of interpolated points, feasible to be used directly with [image](#) and [contour](#):

x	vector of x coordinates of the output grid.
y	vector of y coordinates of the output grid.
z	matrix of interpolated data for the output grid.

Note

Use [interp](#) for the general case of irregular gridded data!

franke.data

Test datasets from Franke for interpolation of scattered data

Description

franke.data generates the test datasets from Franke, 1979, see references.

Usage

```
franke.data(fn = 1, ds = 1, data)
franke.fn(x, y, fn = 1)
```

Arguments

fn	function number, from 1 to 5.
x	'x' value
y	'y' value
ds	data set number, from 1 to 3. Dataset 1 consists of 100 points, dataset 2 of 33 points and dataset 3 of 25 points scattered in the square $[0, 1] \times [0, 1]$. (and partially slightly outside).
data	A list of dataframes with 'x' and 'y' to choose from, dataset franke should be used here.

Details

These datasets are mentioned in [Akima 1996] as testbed for the irregular scattered data interpolator. Franke used the five functions:

$$0.75e^{-\frac{(9x-2)^2+(9y-2)^2}{4}} + 0.75e^{-\frac{(9x+1)^2}{49} - \frac{9y+1}{10}} + 0.5e^{-\frac{(9x-7)^2+(9y-3)^2}{4}} - 0.2e^{-((9x-4)^2-(9y-7)^2)}$$

$$\frac{\tanh(9y - 9x) + 1}{9}$$

$$\frac{1.25 + \cos(5.4y)}{6(1 + (3x - 1)^2)}$$

$$e^{-\frac{81((x-0.5)^2 + \frac{(y-0.5)^2}{16})}{3}}$$

$$e^{-\frac{81((x-0.5)^2 + \frac{(y-0.5)^2}{4})}{3}}$$

$$\frac{\sqrt{64 - 81((x - 0.5)^2 + (y - 0.5)^2)}}{9} - 0.5$$

and evaluated them on different more or less dense grids over $[0, 1] \times [0, 1]$.

Value

A data frame with components

x	'x' coordinate
y	'y' coordinate
z	'z' value

Note

The datasets have to be generated via franke.data before use, the dataset franke only contains a list of 3 dataframes of 'x' and 'y' coordinates for the above mentioned irregular grids. Do not forget to load the franke dataset first.

The 'x' and 'y' values have been taken out of [Akima 1996].

interp

Gridded Bivariate Interpolation for Irregular Data

Description

These functions implement bivariate interpolation onto a grid for irregularly spaced input data. Bilinear or bicubic spline interpolation is applied using different versions of algorithms from Akima.

Usage

```
interp(x, y=NULL, z, xo=seq(min(x), max(x), length = nx),
       yo=seq(min(y), max(y), length = ny),
       linear = TRUE, extrap=FALSE, duplicate = "error", dupfun = NULL,
       nx = 40, ny = 40,
       jitter = 10^-12, jitter.iter = 6, jitter.random = FALSE)
```

Arguments

- x vector of x-coordinates of data points or a `SpatialPointsDataFrame` object. Missing values are not accepted.
- y vector of y-coordinates of data points. Missing values are not accepted. If left as `NULL` indicates that `x` should be a `SpatialPointsDataFrame` and `z` names the variable of interest in this dataframe.
- z vector of z-coordinates of data points or a character variable naming the variable of interest in the `SpatialPointsDataFrame` `x`. Missing values are not accepted.
`x`, `y`, and `z` must be the same length (except if `x` is a `SpatialPointsDataFrame`) and may contain no fewer than four points. The points of `x` and `y` should not be collinear, i.e, they should not fall on the same line (two vectors `x` and `y` such

that $y = ax + b$ for some a, b will not produce meaningful results). Some heuristics is built in to avoid this case by adding small jitter to x and y when the number of NA values in the result exceeds 10%.

`interp` is meant for cases in which you have x, y values scattered over a plane and a z value for each. If, instead, you are trying to evaluate a mathematical function, or get a graphical interpretation of relationships that can be described by a polynomial, try `outer()`.

<code>xo</code>	vector of x-coordinates of output grid. The default is 40 points evenly spaced over the range of x . If extrapolation is not being used (<code>extrap=FALSE</code> , the default), <code>xo</code> should have a range that is close to or inside of the range of x for the results to be meaningful.
<code>yo</code>	vector of y-coordinates of output grid; analogous to <code>xo</code> , see above.
<code>linear</code>	logical – indicating whether linear or spline interpolation should be used.
<code>extrap</code>	logical flag: should extrapolation be used outside of the convex hull determined by the data points?
<code>duplicate</code>	character string indicating how to handle duplicate data points. Possible values are " <code>error</code> " produces an error message, " <code>strip</code> " remove duplicate z values, " <code>mean</code> ", " <code>median</code> ", " <code>user</code> " calculate mean, median or user defined function (<code>dupfun</code>) of duplicate z values.
<code>dupfun</code>	a function, applied to duplicate points if <code>duplicate= "user"</code> .
<code>nx</code>	dimension of output grid in x direction
<code>ny</code>	dimension of output grid in y direction
<code>jitter</code>	Jitter of amount of $\text{diff}(\text{range}(XX)) * \text{jitter}$ ($XX=x$ or y) will be added to coordinates if collinear points are detected. Afterwards interpolation will be tried once again. Note that the jitter is not generated randomly unless <code>jitter.random</code> is set to <code>TRUE</code> . This ensures reproducible result. <code>tri.mesh</code> of package <code>tripack</code> uses the same jitter mechanism. That means you can plot the triangulation on top of the interpolation and see the same triangulation as used for interpolation, see examples below.
<code>jitter.iter</code>	number of iterations to retry with jitter, amount will be multiplied in each iteration by <code>iter^1.5</code>
<code>jitter.random</code>	logical, see <code>jitter</code> , defaults to <code>FALSE</code>

Details

If `linear` is `TRUE` (default), linear interpolation is used in the triangles bounded by data points. Cubic interpolation is done if `linear` is set to `FALSE`. If `extrap` is `FALSE`, z -values for points outside the convex hull are returned as NA. No extrapolation can be performed for the linear case.

The `interp` function handles duplicate (x, y) points in different ways. As default it will stop with an error message. But it can give duplicate points an unique z value according to the parameter `duplicate` (`mean`, `median` or any other user defined function).

The triangulation scheme used by `interp` works well if `x` and `y` have similar scales but will appear stretched if they have very different scales. The spreads of `x` and `y` must be within four orders of magnitude of each other for `interp` to work.

Value

list with 3 components:

<code>x,y</code>	vectors of <code>x</code> - and <code>y</code> - coordinates of output grid, the same as the input argument <code>xo</code> , or <code>yo</code> , if present. Otherwise, their default, a vector 40 points evenly spaced over the range of the input <code>x</code> .
<code>z</code>	matrix of fitted <code>z</code> -values. The value <code>z[i,j]</code> is computed at the <code>x,y</code> point <code>xo[i]</code> , <code>yo[j]</code> . <code>z</code> has dimensions <code>length(xo)</code> times <code>length(yo)</code> .

If input is a `SpatialPointsDataFrame` a `SpatialPixelssDataFrame` is returned.

Note

`interp` uses Akima's new Fortran code from 1996 for spline interpolation, the triangulation (based on Renka's `tripack`) is reused for linear interpolation. In this newer version Akima switched from his own triangulation to Renka's `tripack` (=TOMS 751).

Note that S-Plus uses (used?) the old Fortran code from Akima 1978.

The resulting structure is suitable for input to the functions `contour` and `image`. Check the requirements of these functions when choosing values for `xo` and `yo`.

        ylab="random jitter added",

```

```

        sub="Akimas irregular grid version, ACM 761")
    }
par(old.par)

## End(Not run)
### Use all datasets from Franke, 1979:
data(franke)
for(i in 1:5)
  for(j in 1:3){
    FR <- franke.data(i,j,franke)
    IL <- with(FR, interp(x,y,z,linear=FALSE))
    image(IL)
    contour(IL,add=TRUE)
    with(FR,points(x,y))
  }

```

 interp.old

Gridded Bivariate Interpolation for Irregular Data

Description

These functions implement bivariate interpolation onto a grid for irregularly spaced input data. These functions are only for backward compatibility, use [interp](#) instead.

Usage

```

interp.old(x, y, z, xo= seq(min(x), max(x), length = 40),
           yo=seq(min(y), max(y), length = 40), ncp = 0,
           extrap=FALSE, duplicate = "error", dupfun = NULL)
interp.new(x, y, z, xo = seq(min(x), max(x), length = 40),
           yo = seq(min(y), max(y), length = 40), linear = FALSE,
           ncp = NULL, extrap=FALSE, duplicate = "error", dupfun = NULL)

```

Arguments

- x vector of x-coordinates of data points or a `SpatialPointsDataFrame` object. Missing values are not accepted.
- y vector of y-coordinates of data points. Missing values are not accepted.
If left as `NULL` indicates that x should be a `SpatialPointsDataFrame` and z names the variable of interest in this dataframe.
- z vector of z-coordinates of data points or a character variable naming the variable of interest in the `SpatialPointsDataFrame` x.
Missing values are not accepted.
x, y, and z must be the same length (except if x is a `SpatialPointsDataFrame`) and may contain no fewer than four points. The points of x and y cannot be collinear, i.e, they cannot fall on the same line (two vectors x and y such that

$y = ax + b$ for some a, b will not be accepted). `interp` is meant for cases in which you have x, y values scattered over a plane and a z value for each. If, instead, you are trying to evaluate a mathematical function, or get a graphical interpretation of relationships that can be described by a polynomial, try `outer()`.

<code>xo</code>	vector of x-coordinates of output grid. The default is 40 points evenly spaced over the range of x . If extrapolation is not being used (<code>extrap=FALSE</code> , the default), <code>xo</code> should have a range that is close to or inside of the range of x for the results to be meaningful.
<code>yo</code>	vector of y-coordinates of output grid; analogous to <code>xo</code> , see above.
<code>linear</code>	logical – indicating whether linear or spline interpolation should be used. supersedes old <code>ncp</code> parameter
<code>ncp</code>	deprecated, use parameter <code>linear</code> . Now only used by <code>interp.old()</code> . old meaning was: number of additional points to be used in computing partial derivatives at each data point. <code>ncp</code> must be either 0 (partial derivatives are not used), or at least 2 but smaller than the number of data points (and smaller than 25).
<code>extrap</code>	logical flag: should extrapolation be used outside of the convex hull determined by the data points?
<code>duplicate</code>	character string indicating how to handle duplicate data points. Possible values are <code>"error"</code> produces an error message, <code>"strip"</code> remove duplicate z values, <code>"mean", "median", "user"</code> calculate mean, median or user defined function (<code>dupfun</code>) of duplicate z values.
<code>dupfun</code>	a function, applied to duplicate points if <code>duplicate= "user"</code> .

Details

see [interp](#)

Value

list with 3 components:

<code>x,y</code>	vectors of x - and y - coordinates of output grid, the same as the input argument <code>xo</code> , or <code>yo</code> , if present. Otherwise, their default, a vector 40 points evenly spaced over the range of the input x .
<code>z</code>	matrix of fitted z -values. The value <code>z[i, j]</code> is computed at the x, y point <code>xo[i], yo[j]</code> . <code>z</code> has dimensions <code>length(xo)</code> times <code>length(yo)</code> .

If input is a `SpatialPointsDataFrame` a `SpatialPixelssDataFrame` is returned.

Note

`interp.new` is deprecated and `interp.old` will soon be deprecated.

interp2xyz

From interp() Result, Produce 3-column Matrix

Description

From an [interp\(\)](#) result, produce a 3-column matrix or [data.frame](#) `cbind(x, y, z)`.

Usage

```
interp2xyz(al, data.frame = FALSE)
```

Arguments

`al` a [list](#) as produced from [interp\(\)](#).

`data.frame` logical indicating if result should be [data.frame](#) or matrix (default).

Value

a matrix (or [data.frame](#)) with three columns, called "x", "y", "z".

Author(s)

Martin Maechler, Jan.18, 2013

See Also

[expand.grid\(\)](#) is the “essential ingredient” of [interp2xyz\(\)](#).

[interp](#).

Examples

```

data(akima)
ak.spl <- with(akima, interp(x, y, z, linear = FALSE,
                           xo= seq(0,25, length=100),
                           yo= seq(0,20, length= 96)))
str(ak.spl)# list (x[i], y[j], z = <matrix>[i,j])

## Now transform to simple (x,y,z) matrix / data.frame :
str(am <- interp2xyz(ak.spl))
str(ad <- interp2xyz(ak.spl, data.frame=TRUE))
## and they are the same:
stopifnot( am == ad | (is.na(am) & is.na(ad)) )

```

interpp

Pointwise Bivariate Interpolation for Irregular Data

Description

These functions implement bivariate interpolation onto a set of points for irregularly spaced input data. These functions are only for backward compatibility, use [interpp](#) instead.

If `linear` is `TRUE`, linear interpolation is used in the triangles bounded by data points, otherwise cubic interpolation is done.

If `extrap` is `FALSE`, z-values for points outside the convex hull are returned as NA. No extrapolation can be performed for linear interpolation.

The `interpp` function handles duplicate (x,y) points in different ways. As default it will stop with an error message. But it can give duplicate points an unique z value according to the parameter `duplicate` (mean,median or any other user defined function).

The triangulation scheme used by `interp` works well if x and y have similar scales but will appear stretched if they have very different scales. The spreads of x and y must be within four orders of magnitude of each other for `interp` to work.

Usage

```

interpp(x, y=NULL, z, xo, yo=NULL, linear=TRUE, extrap=FALSE,
        duplicate = "error", dupfun = NULL,
        jitter = 10^-12, jitter.iter = 6, jitter.random = FALSE)

```

Arguments

- x vector of x-coordinates of data points or a `SpatialPointsDataFrame` object. Missing values are not accepted.
- y vector of y-coordinates of data points. Missing values are not accepted.
If left as `NULL` indicates that x should be a `SpatialPointsDataFrame` and z names the variable of interest in this dataframe.

<code>z</code>	vector of z-coordinates of data points or a character variable naming the variable of interest in the <code>SpatialPointsDataFrame</code> <code>x</code> . Missing values are not accepted. <code>x</code> , <code>y</code> , and <code>z</code> must be the same length (except if <code>x</code> is a <code>SpatialPointsDataFrame</code>) and may contain no fewer than four points. The points of <code>x</code> and <code>y</code> cannot be collinear, i.e, they cannot fall on the same line (two vectors <code>x</code> and <code>y</code> such that $y = ax + b$ for some <code>a</code> , <code>b</code> will not be accepted).
<code>xo</code>	vector of x-coordinates of points at which to evaluate the interpolating function. If <code>x</code> is a <code>SpatialPointsDataFrame</code> this has also to be a <code>SpatialPointsDataFrame</code> .
<code>yo</code>	vector of y-coordinates of points at which to evaluate the interpolating function. If operating on <code>SpatialPointsDataFrames</code> this is left as <code>NULL</code>
<code>linear</code>	logical – indicating whether linear or spline interpolation should be used.
<code>extrap</code>	logical flag: should extrapolation be used outside of the convex hull determined by the data points? Not possible for linear interpolation.
<code>duplicate</code>	indicates how to handle duplicate data points. Possible values are "error" - produces an error message, "strip" - remove duplicate z values, "mean", "median", "user" - calculate mean, median or user defined function of duplicate z values.
<code>dupfun</code>	this function is applied to duplicate points if <code>duplicate="user"</code>
<code>jitter</code>	Jitter of amount of <code>diff(range(XX))*jitter</code> (<code>XX=x</code> or <code>y</code>) will be added to coordinates if collinear points are detected. Afterwards interpolation will be tried once again. Note that the jitter is not generated randomly unless <code>jitter.random</code> is set to <code>TRUE</code> . This ensures reproducible result. <code>tri.mesh</code> of package <code>tripack</code> uses the same jitter mechanism. That means you can plot the triangulation on top of the interpolation and see the same triangulation as used for interpolation, see examples below.
<code>jitter.iter</code>	number of iterations to retry with jitter, amount will be increased in each iteration by <code>iter^1.5</code>
<code>jitter.random</code>	logical, see <code>jitter</code> , defaults to <code>FALSE</code>

Value

list with 3 components:

<code>x</code>	vector of x-coordinates of output points, the same as the input argument <code>xo</code> .
<code>y</code>	vector of y-coordinates of output points, the same as the input argument <code>yo</code> .
<code>z</code>	fitted z-values. The value <code>z[i]</code> is computed at the <code>x,y</code> point <code>x[i]</code> , <code>y[i]</code> .

If input is `SpatialPointsDataFrame` than an according `SpatialPointsDataFrame` is returned.

NOTE

Use `interp` if interpolation on a regular grid is wanted.

See [interp](#) for more details.

## End(Not run)
```

Description

If `ncp` is zero, linear interpolation is used in the triangles bounded by data points. Cubic interpolation is done if partial derivatives are used. If `extrap` is `FALSE`, `z`-values for points outside the convex hull are returned as `NA`. No extrapolation can be performed if `ncp` is zero.

The `interpp` function handles duplicate (x, y) points in different ways. As default it will stop with an error message. But it can give duplicate points an unique z value according to the parameter `duplicate` (`mean`, `median` or any other user defined function).

The triangulation scheme used by `interp` works well if x and y have similar scales but will appear stretched if they have very different scales. The spreads of x and y must be within four orders of magnitude of each other for `interpp` to work.

Usage

```
interpp.old(x, y, z, xo, yo, ncp = 0, extrap = FALSE,
            duplicate = "error", dupfun = NULL)
interpp.new(x, y, z, xo, yo, extrap = FALSE,
            duplicate = "error", dupfun = NULL)
```

Arguments

<code>x</code>	vector of x -coordinates of data points or a <code>SpatialPointsDataFrame</code> object. Missing values are not accepted.
<code>y</code>	vector of y -coordinates of data points. Missing values are not accepted. If left as <code>NULL</code> indicates that <code>x</code> should be a <code>SpatialPointsDataFrame</code> and <code>z</code> names the variable of interest in this dataframe.
<code>z</code>	vector of z -coordinates of data points or a character variable naming the variable of interest in the <code>SpatialPointsDataFrame</code> <code>x</code> . Missing values are not accepted. <code>x</code> , <code>y</code> , and <code>z</code> must be the same length (except if <code>x</code> is a <code>SpatialPointsDataFrame</code>) and may contain no fewer than four points. The points of <code>x</code> and <code>y</code> cannot be collinear, i.e. they cannot fall on the same line (two vectors <code>x</code> and <code>y</code> such that $y = ax + b$ for some <code>a</code> , <code>b</code> will not be accepted).
<code>xo</code>	vector of x -coordinates of points at which to evaluate the interpolating function. If <code>x</code> is a <code>SpatialPointsDataFrame</code> this has also to be a <code>SpatialPointsDataFrame</code> .
<code>yo</code>	vector of y -coordinates of points at which to evaluate the interpolating function. If operating on <code>SpatialPointsDataFrames</code> this is left as <code>NULL</code>
<code>ncp</code>	deprecated, use parameter <code>linear</code> . Now only used by <code>interpp.old()</code> . meaning was: number of additional points to be used in computing partial derivatives at each data point. <code>ncp</code> must be either 0 (partial derivatives are not used, = linear interpolation), or at least 2 but smaller than the number of data points (and smaller than 25).
<code>extrap</code>	logical flag: should extrapolation be used outside of the convex hull determined by the data points?
<code>duplicate</code>	indicates how to handle duplicate data points. Possible values are "error" - produces an error message, "strip" - remove duplicate z values, "mean", "median", "user" - calculate mean, median or user defined function of duplicate z values.
<code>dupfun</code>	this function is applied to duplicate points if <code>duplicate="user"</code>

Value

list with 3 components:

x	vector of x-coordinates of output points, the same as the input argument <code>xo</code> .
y	vector of y-coordinates of output points, the same as the input argument <code>yo</code> .
z	fitted z-values. The value <code>z[i]</code> is computed at the x,y point <code>x[i]</code> , <code>y[i]</code> .

If input is `SpatialPointsDataFrame` than an according `SpatialPointsDataFrame` is returned.

NOTE

Use `interp` if interpolation on a regular grid is wanted.

The two versions `interpp.old` and `interpp.new` are now deprecated, use [interpp](#) instead, see details there.

Earlier versions (pre 0.5-1) of `interpp` used the parameter `ncp` to choose between linear and cubic interpolation, this is now done by setting the logical parameter `linear`. Use of `ncp` is still possible, but is deprecated.
