Package ‘blogdown’

March 4, 2020

Type Package

Title Create Blogs and Websites with R Markdown

Version 0.18

Description Write blog posts and web pages in R Markdown. This package supports the static site generator 'Hugo' (<https://gohugo.io>) best, and it also supports 'Jekyll' (<http://jekyllrb.com>) and 'Hexo' (<https://hexo.io>).

License GPL-3

Imports rmarkdown (>= 1.16), bookdown (>= 0.14), knitr (>= 1.25), htmltools, yaml (>= 2.1.19), httpuv (>= 1.4.0), xfun (>= 0.10), servr (>= 0.15)

Suggests testit, shiny, miniUI, stringr, rstudioapi, tools, processx, later, whoami

LazyData true

URL https://github.com/rstudio/blogdown

BugReports https://github.com/rstudio/blogdown/issues

SystemRequirements Hugo (<https://gohugo.io>) and Pandoc (<https://pandoc.org>)

RoxygenNote 7.0.2

Encoding UTF-8

NeedsCompilation no

Author Yihui Xie [aut, cre] (<https://orcid.org/0000-0003-0645-5666>), Beilei Bian [ctb], Forest Fang [ctb], Garrick Aden-Buie [ctb], Hiroaki Yutani [ctb], Ian Lyttle [ctb], JJ Allaire [ctb], Kevin Ushey [ctb], Leonardo Collado-Torres [ctb], Xianying Tan [ctb], Raniere Silva [ctb],
blogdown

The comprehensive documentation of this package is the book *blogdown: Creating Websites with R Markdown* ([https://bookdown.org/yihui/blogdown/](https://bookdown.org/yihui/blogdown/)). You are expected to read at least the first chapter. If you are really busy or do not care about an introduction to blogdown (e.g., you are very familiar with creating websites), set your working directory to an empty directory, and run blogdown::new_site() to get started right away.

Examples

```r
if (interactive()) blogdown::new_site()
```
**build_dir**

---

**Build all Rmd files under a directory**

---

**Description**

List all Rmd files recursively under a directory, and compile them using `rmarkdown::render()`.

**Usage**

```r
build_dir(dir = ".", force = FALSE, ignore = "[.]Rproj$")
```

**Arguments**

- **dir** A directory path.
- **force** Whether to force building all Rmd files. By default, an Rmd file is built only if it is newer than its output file(s).
- **ignore** A regular expression to match output filenames that should be ignored when testing if the modification time of the Rmd source file is newer than its output files.

---

**build_site**

---

**Build a website**

---

**Description**

Compile all Rmd files and build the site through Hugo.

**Usage**

```r
build_site(local = FALSE, method = c("html", "custom"), run_hugo = TRUE)
```

**Arguments**

- **local** Whether to build the website locally to be served via `serve_site()`.
- **method** Different methods to build a website (each with pros and cons). See Details. The value of this argument will be obtained from the global option `getOption('blogdown.method')` when it is set.
- **run_hugo** Whether to run `hugo_build()` after R Markdown files are compiled.
You can use `serve_site()` to preview your website locally, and `build_site()` to build the site for publishing.

For the `method` argument: `method = "html"` means to render all Rmd files to HTML via `rmarkdown::render()` (which means Markdown is processed through Pandoc), and process the paths of external dependencies generated from R code chunks, including images and HTML dependencies.

For all rendering methods, a custom R script ‘R/build.R’ will be executed if you have provided it under the root directory of the website (e.g. you can compile Rmd to Markdown through `knitr::knit()` and build the side via `hugo_cmd()`). `method = "custom"` means it is entirely up to this R script how a website is rendered. The script is executed via command line `Rscript "R/build.R"`, which means it is executed in a separate R session. The value of the argument `local` is passed to the command line (you can retrieve the command-line arguments via `commandArgs(TRUE)`).

**Note**

This function recompiles all R Markdown files by default, even if the output files are newer than the source files. If you want to build the site without rebuilding all R Markdown files, you should use `hugo_build()` instead.

---

**dep_path**

* A helper function to return a dependency path name

**Description**

In most cases, blogdown can process images and HTML widgets automatically generated from code chunks (they will be moved to the static/ folder by default), but it may fail to recognize dependency files generated to other paths. This function returns a path that you can use for your output files, so that blogdown knows that they should be be processed, too. It is designed to be used in a `knitr` code chunk.

**Usage**

```r
dep_path(default = knitr::opts_chunk$get("fig.path"))
```

**Arguments**

- `default` Return this default value when this function is called outside of a `knitr` code chunk.

**Value**

A character string of the default value (outside `knitr`), or a path consisting of the `knitr` figure path appended by the current chunk label.
**find_yaml**  

*Find posts containing the specified metadata*

**Description**

Given a YAML field name, find the (R) Markdown files that contain this field and its value contains any of the specified values. Functions `find_tags()` and `find_categories()` are wrappers of `find_yaml()` with `field = 'tags'` and `field = 'categories'`, respectively; `count_fields()` returns the frequency tables of the specified YAML fields, such as the counts of tags and categories.

**Usage**

```r
find_yaml(field = character(), value = character(), open = FALSE)
find_tags(value = character(), open = FALSE)
find_categories(value = character(), open = FALSE)
count_yaml(fields = c("categories", "tags"), sort_by_count = TRUE)
```

**Arguments**

- `field, fields`: A character vector of YAML field names.
- `value`: A vector of the field values to be matched.
- `open`: Whether to open the matched files automatically.
- `sort_by_count`: Whether to sort the frequency tables by counts.

**Value**

- `find_yaml()` returns a character vector of filenames; `count_yaml()` returns a list of frequency tables.

**Examples**

```r
library(blogdown)
find_tags(c("time-series", "support vector machine"))
find_categories("Statistics")
count_yaml(sort_by_count = FALSE)
```
An R Markdown output format for blogdown web pages

Description

This function is a simple wrapper of bookdown::html_document2() with different default arguments, and more importantly, a special HTML template designed only for blogdown to render R Markdown to HTML pages that can be processed by Hugo.

Usage

```r
html_page(  
  ...,  
  number_sections = FALSE,  
  self_contained = FALSE,  
  highlight = NULL,  
  template = NULL,  
  pre_knit = NULL,  
  post_processor = NULL
)
```

Arguments

```r
..., number_sections, self_contained, highlight, template
Arguments passed to bookdown::html_document2() (note the option theme is not supported and set to NULL internally, and when template = NULL, a default template in blogdown will be used).

pre_knit, post_processor
Passed to rmarkdown::output_format.
```

Details

The HTML output is not a complete HTML document, and only meaningful to blogdown (it will be post-processed to render valid HTML pages). The only purpose of this output format is for users to change options in YAML.

The fact that it is based on bookdown means most bookdown features are supported, such as numbering and cross-referencing figures/tables.

Note

Do not use a custom template unless you understand how the default template actually works (see the blogdown book).

The argument highlight does not support the value "textmate", and the argument template does not support the value "default".
**hugo_cmd**

**References**

---

**hugo_cmd**

*Run Hugo commands*

**Description**

Wrapper functions to run Hugo commands via `system2('hugo',...)`.

**Usage**

hugo_cmd(...)

hugo_version()

hugo_build(local = FALSE)

new_site(
  dir = ".",
  install_hugo = TRUE,
  format = "toml",
  sample = TRUE,
  theme = "yihui/hugo-lithium",
  hostname = "github.com",
  theme_example = TRUE,
  empty_dirs = FALSE,
  to_yaml = TRUE,
  serve = interactive()
)

new_content(path, kind = "", open = interactive())

new_post(
  title,
  kind = "",
  open = interactive(),
  author = getOption("blogdown.author"),
  categories = NULL,
  tags = NULL,
  date = Sys.Date(),
  file = NULL,
  slug = NULL,
  title_case = getOption("blogdown.title_case"),
  subdir = getOption("blogdown.subdir", "post"),
ext = getOption("blogdown.ext", ".md")

hugo_convert(to = c("YAML", "TOML", "JSON"), unsafe = FALSE, ...)

hugo_server(host, port)

Arguments

... Arguments to be passed to system2(‘hugo’, ...), e.g. new_content(path) is basically hugo_cmd(c(‘new’, path)) (i.e. run the command hugo new path).

local Whether to build the site for local preview (if TRUE, all drafts and future posts will also be built, and the site configuration baseurl will be set to / temporarily).

dir The directory of the new site. It should be empty or only contain hidden files, RStudio project (’*.Rproj’) files, ‘LICENSE’, and/or ‘README’/’README.md’.

install_hugo Whether to install Hugo automatically if it is not found.

format The format of the configuration file. Note that the frontmatter of the new (R) Markdown file created by new_content() always uses YAML instead of TOML.

sample Whether to add sample content. Hugo creates an empty site by default, but this function adds sample content by default.

theme A Hugo theme on Github (a character string of the form user/repo, and you can optionally specify a GIT branch or tag name after @, i.e. theme can be of the form user/repo@branch). You can also specify a full URL to the zip file of the theme. If theme = NA, no themes will be installed, and you have to manually install a theme.

hostname Where to find the theme. Defaults to github.com; specify if you wish to use an instance of GitHub Enterprise. You can also specify the full URL of the zip file in theme, in which case this argument is ignored.

theme_example Whether to copy the example in the ‘exampleSite’ directory if it exists in the theme. Not all themes provide example sites.

empty_dirs Whether to keep the empty directories generated by Hugo.

to_yaml Whether to convert the metadata of all posts to YAML.

serve Whether to start a local server to serve the site.

path The path to the new file under the ‘content’ directory.

kind The content type to create, i.e., the Hugo archetype. If the archetype is a page bundle archetype, it should end with a slash, e.g., post/.

open Whether to open the new file after creating it. By default, it is opened in an interactive R session.

title The title of the post.

author The author of the post.

categories A character vector of category names.

tags A character vector of tag names.
**hugo_cmd**

- **date**: The date of the post.
- **file**: The filename of the post. By default, the filename will be automatically generated from the title by replacing non-alphanumeric characters with dashes, e.g., title = 'Hello World' may create a file 'content/post/2016-12-28-hello-world.md'. The date of the form YYYY-mm-dd will be prepended if the filename does not start with a date.
- **slug**: The slug of the post. By default (NULL), the slug is generated from the filename by removing the date and filename extension, e.g., if file = 'post/2015-07-23-hi-there.md', slug will be hi-there. Set slug = ' ' if you do not want it.
- **title_case**: A function to convert the title to title case. If TRUE, the function is `tools::toTitleCase()`. This argument is not limited to title case conversion. You can provide an arbitrary R function to convert the title.
- **subdir**: If specified (not NULL), the post will be generated under a subdirectory under `content/`. It can be a nested subdirectory like 'post/joe/'.
- **ext**: The filename extension (e.g., '.md', '.Rmd', or '.Rmarkdown'). Ignored if file has been specified.
- **to**: A format to convert to.
- **unsafe**: Whether to enable unsafe operations, such as overwriting Markdown source documents. If you have backed up the website, or the website is under version control, you may try unsafe = TRUE.
- **host, port**: The host IP address and port; see `servr::server_config()`.

**Functions**

- **hugo_cmd**: Run an arbitrary Hugo command.
- **hugo_version**: Return the version number of Hugo if possible, which is extracted from the output of `hugo_cmd('version')`.
- **hugo_build**: Build a plain Hugo website. Note that the function `build_site()` first compiles Rmd files, and then calls Hugo via `hugo_build()` to build the site.
- **new_site**: Create a new site (skeleton) via `hugo new site`. The directory of the new site should be empty.
- **new_content**: Create a new (R) Markdown file via hugo new (e.g. a post or a page).
- **new_post**: A wrapper function to create a new post under the `content/post/` directory via `new_content()`. If your post will use R code chunks, you can set ext = '.Rmd' or the global option options(blogdown.ext = '.Rmd') in your `~/.Rprofile`. Similarly, you can set options(blogdown.author = 'Your Name') so that the author field is automatically filled out when creating a new post.
- **hugo_convert**: A wrapper function to convert source content to different formats via `hugo convert`.
- **hugo_server**: Start a Hugo server.

**References**

The full list of Hugo commands: [https://gohugo.io/commands](https://gohugo.io/commands), and themes: [http://themes.gohugo.io](http://themes.gohugo.io).
install_hugo

Examples

```r
library(blogdown)
if (interactive()) new_site()
```

install_hugo Install Hugo

Description

Download the appropriate Hugo executable for your platform from Github and try to copy it to a system directory so `blogdown` can run the `hugo` command to build a site. `update_hugo()` is a wrapper of `install_hugo(force = TRUE)`.

Usage

```r
install_hugo(
  version = "latest",
  use_brew = Sys.which("brew") != "",
  force = FALSE,
  extended = TRUE
)
```

Arguments

- `version` The Hugo version number, e.g., `0.26`; the special value `latest` means the latest version (fetched from Github releases). Alternatively, this argument can take a file path of the zip archive or tarball of the Hugo installer that has already been downloaded from Github, in which case it will not be downloaded again.
- `use_brew` Whether to use Homebrew ([https://brew.sh](https://brew.sh)) on macOS to install Hugo (recommended if you have already installed Homebrew). Note Homebrew will be automatically installed if it has not been installed when `use_brew = TRUE`.
- `force` Whether to install Hugo even if it has already been installed. This may be useful when upgrading Hugo (if you use Homebrew, run the command `brew update` & `brew upgrade` instead).
- `extended` Whether to use extended version of Hugo that has SCSS/SASS support. You only need the extended version if you want to edit SCSS/SASS.

Details

This function tries to install Hugo to `Sys.getenv('APPDATA')` on Windows, `~/Library/Application Support` on macOS, and `~/.bin/` on other platforms (such as Linux). If these directories are not writable, the package directory ‘Hugo’ of `blogdown` will be used. If it still fails, you have to install Hugo by yourself and make sure it can be found via the environment variable `PATH`. 
install_theme

This is just a helper function and may fail to choose the correct Hugo executable for your operating system, especially if you are not on Windows or Mac or a major Linux distribution. When in doubt, read the Hugo documentation and install it by yourself: https://gohugo.io.

If you want to install Hugo to a custom path, you can set the global option blogdown.hugo.dir to a directory to store the Hugo executable before you call install_hugo(), e.g., options(blogdown.hugo.dir = '~/Downloads/hugo_0.20.1/'). This may be useful for you to use a specific version of Hugo for a specific website. You can set this option per project. See Section 1.4 Global options for details, or store a copy of Hugo on a USB Flash drive along with your website.

install_theme  Install a Hugo theme from Github

Description

Download the specified theme from Github and install to the ‘themes’ directory. Available themes are listed at http://themes.gohugo.io.

Usage

install_theme(
  theme,
  hostname = "github.com",
  theme_example = FALSE,
  update_config = TRUE,
  force = FALSE,
  update_hugo = TRUE
)

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>theme</td>
<td>A Hugo theme on Github (a character string of the form user/repo, and you can optionally specify a GIT branch or tag name after @, i.e. theme can be of the form user/repo@branch). You can also specify a full URL to the zip file of the theme. If theme = NA, no themes will be installed, and you have to manually install a theme.</td>
</tr>
<tr>
<td>hostname</td>
<td>Where to find the theme. Defaults to github.com; specify if you wish to use an instance of GitHub Enterprise. You can also specify the full URL of the zip file in theme, in which case this argument is ignored.</td>
</tr>
<tr>
<td>theme_example</td>
<td>Whether to copy the example in the ‘exampleSite’ directory if it exists in the theme. Not all themes provide example sites.</td>
</tr>
<tr>
<td>update_config</td>
<td>Whether to update the theme option in the site configurations.</td>
</tr>
<tr>
<td>force</td>
<td>Whether to override the existing theme of the same name. If you have made changes to this existing theme, your changes will be lost when force = TRUE! Please consider backing up the theme by renaming it before you try force = TRUE.</td>
</tr>
<tr>
<td>update_hugo</td>
<td>Whether to automatically update Hugo if the theme requires a higher version of Hugo than the existing version in your system.</td>
</tr>
</tbody>
</table>

**serve_site**  
*Live preview a site*

**Description**

The function `serve_site()` calls `servr::http()` to start a web server, watch for changes in the site, rebuild the site if necessary, and refresh the web page automatically by default; `stop_server()` stops the web server.

**Usage**

```r
serve_site(...)  
stop_server()
```

**Arguments**

```r
...  
```

Arguments passed to `servr::http()` (arguments `dir`, `site.dir`, `baseurl`, and `handler` have been provided, hence you cannot customize these arguments).

**Details**

Alternatively, you can set the global option `options(blogdown.generator.server = TRUE)`, and `serve_site()` will use the web server provided by the static site generator, such as `hugo_server()`. This requires additional packages `processx` and `later`. You may use this option when you primarily work on plain Markdown posts instead of R Markdown posts, because it can be faster to preview Markdown posts using the web server of the static site generator. The web server will always be stopped when the R session is ended, so you may consider restarting your R session if `stop_server` fails to stop the server for some reason.

---

**shortcode**  
*Helper functions to write Hugo shortcodes using the R syntax*

**Description**

These functions return Hugo shortcodes with the shortcode name and arguments you specify. The closing shortcode will be added only if the inner content is not empty. The function `shortcode_html()` is essentially `shortcode(.type = "html")`. The function `shortcodes()` is a vectorized version of `shortcode()`.

**Usage**

```r
shortcode(.name, ..., .content = NULL, .type = "markdown")  
shortcode_html(...)  
shortcodes(..., .sep = "\n")
```
shortcode

Arguments

- `.name` The name of the shortcode.
- `...` All arguments of the shortcode (either all named, or all unnamed). The `...` argument of `shortcode_html()` is passed to `shortcode()`.
- `.content` The inner content for the shortcode.
- `.type` The type of the shortcode: markdown or html.
- `.sep` The separator between two shortcodes (by default, a newline).

Details

These functions can be used in either knitr inline R expressions or code chunks. The returned character string is wrapped in `htmltools::HTML()`, so **rmarkdown** will protect it from the Pandoc conversion. You cannot simply write `{{< shortcode >}}` in R Markdown, because Pandoc is not aware of Hugo shortcodes, and may convert special characters so that Hugo can no longer recognize the shortcodes (e.g. `<` will be converted to `&lt;`). If your document is pure Markdown, you can use the Hugo syntax to write shortcodes, and there is no need to call these R functions.

Value

A character string wrapped in `htmltools::HTML()`; `shortcode()` returns a string of the form `{{% name args %}}`, and `shortcode_html()` returns `{{< name args >}}`.

References

https://gohugo.io/extras/shortcodes/

Examples

```r
library(blogdown)

shortcode("tweet", "1234567")
shortcodes("tweet", as.character(1:5)) # multiple tweets
shortcode("figure", src = "/images/foo.png", alt = "A nice figure")
shortcode("highlight", "bash", .content = "echo hello world;")

shortcode_html("myshortcode", .content = "My <strong>shortcode</strong>.")
```
