

Package ‘difNLR’

January 7, 2021

Type Package

Title DIF and DDF Detection by Non-Linear Regression Models

Version 1.3.7

Date 2021-01-07

Author Adela Hladka [aut, cre],
Patricia Martinkova [aut],
Karel Zvara [ctb]

Maintainer Adela Hladka <hladka@cs.cas.cz>

Depends R (>= 3.1)

Imports calculus, CTT, ggplot2 (>= 2.2.1), grDevices, methods, msm,
nnet, plyr, reshape2, stats, VGAM

Suggests ShinyItemAnalysis

Description Detection of differential item functioning (DIF) among dichotomously scored items and differential distractor functioning (DDF) among un-scored items with non-linear regression procedures based on generalized logistic regression models (Drabinova & Martinkova, 2017, <doi:10.1111/jedm.12158>).

Description

The difNLR package contains method for detection of differential item functioning (DIF) based on non-linear regression. Both uniform and non-uniform DIF effects can be detected when considering one focal group. The method also allows to test the difference in guessing or inattention parameters between reference and focal group. DIF detection method is based either on likelihood-ratio test, F-test, or Wald's test of a submodel. Package also offers methods for detection of differential distractor functioning (DDF) based on multinomial log-linear regression model and newly methods for DIF detection among ordinal data via adjacent category logit and cumulative logit regression models.

Details

Package: difNLR
Type: Package
Version: 1.3.7
Date: 2021-01-07
Depends: R (>= 3.1)
Imports: CTT, ggplot2 (>= 2.2.1), grDevices, methods, msm, nnet, plyr, reshape2, stats, VGAM
Suggests: ShinyItemAnalysis
License: GPL-3
BugReports: <https://github.com/adelahladka/difNLR/issues>
Encoding: UTF-8

checkInterval

Checks interval bounds.

Description

Checks whether x lies in interval defined by bounds in vec . If it does, it returns value of x . In case that value of x is lower than lower bound specified in vec , it returns its value. In case that value of x is greater than upper bound specified in vec , it returns its value.

Usage

```
checkInterval(x, vec)
```

Arguments

x	numeric.
vec	numeric: increasingly sorted bounds of interval.

Examples

```
## Not run:  
checkInterval(x = 0.5, vec = c(0, 1))  
checkInterval(x = 1.5, vec = c(0, 1))  
checkInterval(x = -0.5, vec = c(0, 1))  
  
## End(Not run)
```

coef.ddfMLR *Extract model coefficients from an object of "ddfMLR" class.*

Description

S3 method for extracting estimated model coefficients from an object of "ddfMLR" class.

Usage

```
## S3 method for class 'ddfMLR'  
coef(object, SE = FALSE, simplify = FALSE, ...)
```

Arguments

object	an object of "ddfMLR" class.
SE	logical: should the standard errors of estimated parameters be also returned? (default is FALSE).
simplify	logical: should the estimated parameters be simplified to a matrix? (default is FALSE).
...	other generic parameters for coef() method.

ddfMLR

DDF detection for nominal data.

Description

Performs DDF detection procedure for nominal data based on multinomial log-linear regression model and likelihood ratio test of a submodel.

Usage

```
ddfMLR(Data, group, focal.name, key, type = "both", match = "zscore", anchor = NULL,
        purify = FALSE, nrIter = 10, p.adjust.method = "none", parametrization = "irt",
        alpha = 0.05)
```

Arguments

Data	data.frame or matrix: dataset which rows represent unscored examinee answers (nominal) and columns correspond to the items. In addition, Data can hold the vector of group membership.
group	numeric or character: a dichotomous vector of the same length as nrow(Data) or a column identifier of Data.
focal.name	numeric or character: indicates the level of group which corresponds to focal group.
key	character: the answer key. Each element corresponds to the correct answer of one item.

type	character: type of DDF to be tested. Either "both" for uniform and non-uniform DDF (i.e., difference in parameters "a" and "b") (default), or "udif" for uniform DDF only (i.e., difference in difficulty parameter "b"), or "nudif" for non-uniform DDF only (i.e., difference in discrimination parameter "a"). Can be specified as a single value (for all items) or as an item-specific vector.
match	numeric or character: matching criterion to be used as an estimate of trait. Can be either "zscore" (default, standardized total score), "score" (total test score), or vector of the same length as number of observations in Data.
anchor	numeric or character: specification of DDF free items. Either NULL (default), or a vector of item names (column names of Data), or item identifiers (integers specifying the column number) determining which items are currently considered as anchor (DDF free) items. Argument is ignored if match is not "zscore" or "score".
purify	logical: should the item purification be applied? (default is FALSE).
nrIter	numeric: the maximal number of iterations in the item purification (default is 10).
p.adjust.method	character: method for multiple comparison correction. Possible values are "holm", "hochberg", "hommel", "bonferroni", "BH", "BY", "fdr", and "none" (default). For more details see p.adjust .
parametrization	character: parametrization of regression coefficients. Possible options are "irt" for difficulty-discrimination parametrization (default) and "classic" for intercept-slope parametrization. See Details .
alpha	numeric: significance level (default is 0.05).

Details

Performs DDF detection procedure for nominal data based on multinomial log-linear regression model and likelihood ratio test of submodel. Probability of selection the k -th category (distractor) is

$$P(y = k) = \exp((a_k + a_k \text{Diff} * g) * (x - b_k - b_k \text{Diff} * g)) / (1 + \sum \exp((a_l + a_l \text{Diff} * g) * (x - b_l - b_l \text{Diff} * g))),$$

where x is by default standardized total score (also called Z-score) and g is a group membership. Parameters a_k and b_k are discrimination and difficulty for the k -th category. Terms $a_k \text{Diff}$ and $b_k \text{Diff}$ then represent differences between two groups (reference and focal) in relevant parameters. Probability of correct answer (specified in argument key) is

$$P(y = k) = 1 / (1 + \sum \exp((a_l + a_l \text{Diff} * g) * (x - b_l - b_l \text{Diff} * g))).$$

Parameters are estimated via neural networks. For more details see [multinom](#).

Argument parametrization is a character which specifies parametrization of regression parameters. Default option is "irt" which returns IRT parametrization (difficulty-discrimination, see above). Option "classic" returns intercept-slope parametrization with effect of group membership and interaction with matching criterion, i.e. $b_0k + b_1k * x + b_2k * g + b_3k * x * g$ instead of $(a_k + a_k \text{Diff} * g) * (x - b_k - b_k \text{Diff} * g)$.

Missing values are allowed but discarded for item estimation. They must be coded as NA for both, Data and group arguments.

Value

The `ddfMLR()` function returns an object of class "ddfMLR". The output including values of the test statistics, p-values, and items marked as DDF is displayed by the `print()` method.

A list of class "ddfMLR" with the following arguments:

`Sval` the values of likelihood ratio test statistics.

`m1rPAR` the estimates of final model.

`m1rSE` standard errors of the estimates of final model.

`parM0` the estimates of null model.

`parM1` the estimates of alternative model.

`l1M0` log-likelihood of null model.

`l1M1` log-likelihood of alternative model.

`AIC0` AIC of null model.

`AIC1` AIC of alternative model.

`BIC0` BIC of null model.

`BIC1` BIC of alternative model.

`DDFitems` either the column identifiers of the items which were detected as DDF, or "No DDF item detected" in case no item was detected as DDF.

`type` character: type of DDF that was tested.

`purification` purify value.

`nrPur` number of iterations in item purification process. Returned only if `purify` is TRUE.

`ddfPur` a binary matrix with one row per iteration of item purification and one column per item. "1" in i-th row and j-th column means that j-th item was identified as DDF in i-th iteration. Returned only if `purify` is TRUE.

`conv.puri` logical indicating whether item purification process converged before the maximal number `nrIter` of iterations. Returned only if `purify` is TRUE.

`p.adjust.method` character: method for multiple comparison correction which was applied.

`pval` the p-values by likelihood ratio test.

`adj.pval` the adjusted p-values by likelihood ratio test using `p.adjust.method`.

`df` the degrees of freedom of likelihood ratio test.

`alpha` numeric: significance level.

`Data` the data matrix.

`group` the vector of group membership.

`group.names` levels of grouping variable.

`key` key of correct answers.

`match` matching criterion.

For an object of class "ddfMLR" several methods are available (e.g. `methods(class = "ddfMLR")`).

difNLR

DIF detection using non-linear regression method.

Description

Performs DIF detection procedure for dichotomous data based on non-linear regression model (generalized logistic regression) and either likelihood-ratio test, F-test, or Wald's test of a submodel.

Usage

```

difNLR(
  Data, group, focal.name, model, constraints, type = "all", method = "nls",
  match = "zscore", anchor = NULL, purify = FALSE, nrIter = 10, test = "LR",
  alpha = 0.05, p.adjust.method = "none", start, initboot = TRUE, nrBo = 20,
  sandwich = FALSE
)

```

Arguments

<code>Data</code>	data.frame or matrix: dataset which rows represent scored examinee answers ("1" correct, "0" incorrect) and columns correspond to the items. In addition, <code>Data</code> can hold the vector of group membership.
<code>group</code>	numeric or character: a dichotomous vector of the same length as <code>nrow(Data)</code> or a column identifier of <code>Data</code> .
<code>focal.name</code>	numeric or character: indicates the level of group which corresponds to focal group.
<code>model</code>	character: generalized logistic regression model to be fitted. See Details .
<code>constraints</code>	character: which parameters should be the same for both groups. Possible values are any combinations of parameters "a", "b", "c", and "d". See Details .
<code>type</code>	character: type of DIF to be tested. Possible values are "all" for detecting difference in any parameter (default), "udif" for uniform DIF only (i.e., difference in difficulty parameter "b"), "nudif" for non-uniform DIF only (i.e., difference in discrimination parameter "a"), "both" for uniform and non-uniform DIF (i.e., difference in parameters "a" and "b"), or combination of parameters "a", "b", "c", and "d". Can be specified as a single value (for all items) or as an item-specific vector.
<code>method</code>	character: method used to estimate parameters. Either "nls" for non-linear least squares (default), or "likelihood" for maximum likelihood method.
<code>match</code>	numeric or character: matching criterion to be used as an estimate of trait. Can be either "zscore" (default, standardized total score), "score" (total test score), or vector of the same length as number of observations in <code>Data</code> .
<code>anchor</code>	numeric or character: specification of DIF free items. Either NULL (default), or a vector of item names (column names of <code>Data</code>), or item identifiers (integers specifying the column number) determining which items are currently considered as anchor (DIF free) items. Argument is ignored if <code>match</code> is not "zscore" or "score".
<code>purify</code>	logical: should the item purification be applied? (default is FALSE).
<code>nrIter</code>	numeric: the maximal number of iterations in the item purification (default is 10).
<code>test</code>	character: test to be performed for DIF detection. Can be either "LR" for likelihood ratio test of a submodel (default), "W" for Wald test, or "F" for F-test of a submodel.
<code>alpha</code>	numeric: significance level (default is 0.05).
<code>p.adjust.method</code>	character: method for multiple comparison correction. Possible values are "holm", "hochberg", "hommel", "bonferroni", "BH", "BY", "fdr", and "none" (default). For more details see p.adjust .
<code>start</code>	numeric: initial values for estimation of parameters. If not specified, starting values are calculated with <code>startNLR</code> function. Otherwise, list with as many elements as a number of items. Each element is a named numeric vector of length 8 representing initial values for parameter estimation. Specifically, parameters "a", "b", "c", and "d" are initial values for discrimination, difficulty, guessing,

	and inattention for reference group. Parameters "aDif", "bDif", "cDif", and "dDif" are then differences in these parameters between reference and focal group.
initboot	logical: in case of convergence issues, should be starting values re-calculated based on bootstrapped samples? (default is TRUE; newly calculated initial values are applied only to items/models with convergence issues).
nrBo	numeric: the maximal number of iterations for calculation of starting values using bootstrapped samples (default is 20).
sandwich	logical: should be sandwich estimator used for covariance matrix of parameters when using method = "nls"? Default is FALSE.

Details

DIF detection procedure based on non-linear regression is the extension of the logistic regression procedure (Swaminathan & Rogers, 1990) accounting for possible guessing and/or inattention when responding (Drabinova & Martinkova, 2017; Hladka & Martinkova, 2020).

The unconstrained form of 4PL generalized logistic regression model for probability of correct answer (i.e., $y = 1$) is

$$P(y = 1) = (c + cDif * g) + (d + dDif * g - c - cDif * g) / (1 + \exp(-(a + aDif * g) * (x - b - bDif * g))),$$

where x is by default standardized total score (also called Z-score) and g is a group membership. Parameters a , b , c , and d are discrimination, difficulty, guessing, and inattention. Terms $aDif$, $bDif$, $cDif$, and $dDif$ then represent differences between two groups (reference and focal) in relevant parameters.

This 4PL model can be further constrained by `model` and `constraints` arguments. The arguments `model` and `constraints` can be also combined. Both arguments can be specified as a single value (for all items) or as an item-specific vector (where each element correspond to one item).

The `model` argument offers several predefined models. The options are as follows: Rasch for 1PL model with discrimination parameter fixed on value 1 for both groups, 1PL for 1PL model with discrimination parameter fixed for both groups, 2PL for logistic regression model, 3PLcg for 3PL model with fixed guessing for both groups, 3PLdg for 3PL model with fixed inattention for both groups, 3PLc (alternatively also 3PL) for 3PL regression model with guessing parameter, 3PLd for 3PL model with inattention parameter, 4PLcgdg for 4PL model with fixed guessing and inattention parameter for both groups, 4PLcgd (alternatively also 4PLd) for 4PL model with fixed guessing for both groups, 4PLcdg (alternatively also 4PLc) for 4PL model with fixed inattention for both groups, or 4PL for 4PL model.

The `model` can be specified in more detail with `constraints` argument which specifies what parameters should be fixed for both groups. For example, choice "ad" means that discrimination (parameter "a") and inattention (parameter "d") are fixed for both groups and other parameters ("b" and "c") are not. The NA value for `constraints` means no constraints.

Missing values are allowed but discarded for item estimation. They must be coded as NA for both, Data and group arguments.

In case that model considers difference in guessing or inattention parameter, the different parameterization is used and parameters with standard errors are re-calculated by delta method. However, covariance matrices stick with alternative parameterization.

Value

The `difNLR()` function returns an object of class "difNLR". The output including values of the test statistics, p-values, and items detected as function differently is displayed by the `print()` method.

Object of class "difNLR" is a list with the following components:

`Sval` the values of the test statistics.

`nlrPAR` the estimates of final model.

`nlrSE` the standard errors of estimates of final model.

`parM0` the estimates of null model.

`seM0` the standard errors of estimates of null model.

`covM0` the covariance matrices of estimates of null model.

`llM0` log-likelihood of null model.

`parM1` the estimates of alternative model.

`seM1` the standard errors of estimates of alternative model.

`covM1` the covariance matrices of estimates of alternative model.

`llM1` log-likelihood of alternative model.

`DIFitems` either the column identifiers of the items which were detected as DIF, or "No DIF item detected" in case no item was detected as function differently.

`model` fitted model.

`constraints` constraints for the model.

`type` character: type of DIF that was tested. If parameters were specified, the value is "other".

`types` character: the parameters (specified by user, type has value "other") which were tested for difference.

`p.adjust.method` character: method for multiple comparison correction which was applied.

`pval` the p-values of the test.

`adj.pval` the adjusted p-values of the test using `p.adjust.method`.

`df` the degrees of freedom of the test.

`test` used test.

`purification` purify value.

`nrPur` number of iterations in item purification process. Returned only if `purify` is TRUE.

`difPur` a binary matrix with one row per iteration of item purification and one column per item. "1" in i-th row and j-th column means that j-th item was identified as DIF in i-th iteration. Returned only if `purify` is TRUE.

`conv.puri` logical: indicating whether item purification process converged before the maximal number `nrIter` of iterations. Returned only if `purify` is TRUE.

`method` used estimation method.

`conv.fail` numeric: number of convergence issues.

`conv.fail.which` the identifiers of the items which did not converge.

`alpha` numeric: significance level.

Data the data matrix.
group the vector of group membership.
group.names names of groups.
match matching criterion.

For an object of class "difNLR" several methods are available (e.g., `methods(class = "difNLR")`).

difORD

DIF detection among ordinal data.

Description

Performs DIF detection procedure for ordinal data based either on adjacent category logit model or on cumulative logit model and likelihood ratio test of a submodel.

Usage

```
difORD(Data, group, focal.name, model = "adjacent", type = "both", match = "zscore",
        anchor = NULL, purify = FALSE, nrIter = 10, p.adjust.method = "none",
        parametrization = "irt", alpha = 0.05)
```

Arguments

Data	data.frame or matrix: dataset which rows represent ordinal scored examinee answers and columns correspond to the items. In addition, Data can hold the vector of group membership.
group	numeric or character: a dichotomous vector of the same length as nrow(Data) or a column identifier of Data.
focal.name	numeric or character: indicates the level of group which corresponds to focal group.
model	character: logistic regression model for ordinal data (either "adjacent" (default) or "cumulative"). See Details .
type	character: type of DIF to be tested. Either "both" for uniform and non-uniform DIF (i.e., difference in parameters "a" and "b") (default), or "udif" for uniform DIF only (i.e., difference in difficulty parameter "b"), or "nudif" for non-uniform DIF only (i.e., difference in discrimination parameter "a"). Can be specified as a single value (for all items) or as an item-specific vector.
match	numeric or character: matching criterion to be used as an estimate of trait. Can be either "zscore" (default, standardized total score), "score" (total test score), or vector of the same length as number of observations in Data.
anchor	numeric or character: specification of DIF free items. Either NULL (default), or a vector of item names (column names of Data), or item identifiers (integers specifying the column number) determining which items are currently considered as anchor (DIF free) items. Argument is ignored if match is not "zscore" or "score".
purify	logical: should the item purification be applied? (default is FALSE).
nrIter	numeric: the maximal number of iterations in the item purification (default is 10).
p.adjust.method	character: method for multiple comparison correction. Possible values are "holm", "hochberg", "hommel", "bonferroni", "BH", "BY", "fdr", and "none" (default). For more details see p.adjust .
parametrization	character: parametrization of regression coefficients. Possible options are "irt" for difficulty-discrimination parametrization (default) and "classic" for intercept-slope parametrization. See Details .
alpha	numeric: significance level (default is 0.05).

Details

Performs DIF detection procedure for ordinal data based either on adjacent category logit model or on cumulative logit model.

Using adjacent category logit model, logarithm of ratio of probabilities of two adjacent categories is

$$\log(P(y = k)/P(y = k - 1)) = (a + a_{Dif} * g) * (x - b_k - b_k_{Dif} * g),$$

where x is by default standardized total score (also called Z-score) and g is a group membership. Parameter a is a discrimination of the item and parameter b_k is difficulty for the k -th category of the item. Terms a_{Dif} and b_k_{Dif} then represent differences between two groups (reference and focal) in relevant parameters.

Using cumulative logit model, probability of gaining at least k points is given by 2PL model, i.e.,

$$P(Y \geq k) = \exp((a + a_{Dif} * g) * (x - b_k - b_k_{Dif} * g)) / (1 + \exp((a + a_{Dif} * g) * (x - b_k - b_k_{Dif} * g))).$$

The category probability (i.e., probability of gaining exactly k points) is then $P(Y = k) = P(Y \geq k) - P(Y \geq k + 1)$.

Both models are estimated by iteratively reweighted least squares. For more details see [vg1m](#).

Argument `parametrization` is a character which specifies parametrization of regression parameters. Default option is `"irt"` which returns IRT parametrization (difficulty-discrimination, see above). Option `"classic"` returns intercept-slope parametrization with effect of group membership and interaction with matching criterion, i.e. $b_0k + b_1 * x + b_2k * g + b_3 * x * g$ instead of $(a + a_{Dif} * g) * (x - b_k - b_k_{Dif} * g)$.

Missing values are allowed but discarded for item estimation. They must be coded as NA for both, Data and group parameters.

Value

The `difORD()` function returns an object of class `"difORD"`. The output including values of the test statistics, p-values, and items marked as DIF is displayed by the `print()` method.

A list of class `"difORD"` with the following arguments:

`Sval` the values of likelihood ratio test statistics.

`ordPAR` the estimates of the final model.

`ordSE` standard errors of the estimates of the final model.

`parM0` the estimates of null model.

`parM1` the estimates of alternative model.

`llM0` log-likelihood of null model.

`llM1` log-likelihood of alternative model.

`AICM0` AIC of null model.

`AICM1` AIC of alternative model.

`BICM0` BIC of null model.

`BICM1` BIC of alternative model.

`DIFitems` either the column identifiers of the items which were detected as DIF, or `"No DIF item detected"` in case no item was detected as DIF.

`model` model used for DIF detection.

`type` character: type of DIF that was tested.

parametrization Parameters' parametrization.
 purification purify value.
 nrPur number of iterations in item purification process. Returned only if purify is TRUE.
 difPur a binary matrix with one row per iteration of item purification and one column per item.
 "1" in i-th row and j-th column means that j-th item was identified as DIF in i-th iteration.
 Returned only if purify is TRUE.
 conv.puri logical indicating whether item purification process converged before the maximal
 number nrIter of iterations. Returned only if purify is TRUE.
 p.adjust.method character: method for multiple comparison correction which was applied.
 pval the p-values by likelihood ratio test.
 adj.pval the adjusted p-values by likelihood ratio test using p.adjust.method.
 df the degress of freedom of likelihood ratio test.
 alpha numeric: significance level.
 Data the data matrix.
 group the vector of group membership.
 group.names levels of grouping variable.
 match matching criterion.

For an object of class "difORD" several methods are available (e.g. `methods(class = "difORD")`).

estimNLR

Non-Linear Regression DIF models estimation.

Description

Estimates parameters of non-linear regression models for DIF detection using either non-linear least squares or maximum likelihood method.

Usage

```
estimNLR(y, match, group, formula, method, lower, upper, start)
```

Arguments

y	numeric: binary vector of responses.
match	numeric: vector of matching criterion.
group	numeric: binary vector of group membership. "0" for reference group, "1" for focal group.
formula	formula: specification of the model. Can be obtained by formulaNLR() function.
method	character: method used to estimate parameters. The options are "nls" for non-linear least squares (default) and "likelihood" for maximum likelihood method.
lower	numeric: lower bounds for parameters of model specified in formula.
upper	numeric: upper bounds for parameters of model specified in formula.
start	numeric: initial parameters. Can be obtained by startNLR() function.

```

fitted.difNLR

Fitted values and residuals for an object of "difNLR" class.

Description

S3 methods for extracting fitted values and residuals for an object of "difNLR" class.

Usage

```
## S3 method for class 'difNLR'  
fitted(object, item = "all", ...)  
  
## S3 method for class 'difNLR'  
residuals(object, item = "all", ...)
```

Arguments

object	an object of "difNLR" class.
item	numeric or character: either character "all" to apply for all converged items (default), or a vector of item names (column names of Data), or item identifiers (integers specifying the column number).
...	other generic parameters for S3 methods.

 formulaNLR

Formula for non-linear regression DIF model.

Description

Function returns the formula of the non-linear regression DIF model based on model specification and DIF type to be tested.

Usage

```
formulaNLR(model, constraints = NULL, type = "all", parameterization = "classic", outcome)
```

Arguments

model	character: generalized logistic regression model for which starting values should be estimated. See Details .
constraints	character: which parameters should be the same for both groups. Possible values are any combinations of parameters "a", "b", "c", and "d". Default value is NULL. See Details .
type	character: type of DIF to be tested. Possible values are "all" for detecting difference in any parameter (default), "udif" for uniform DIF only (i.e., difference in difficulty parameter "b"), "nudif" for non-uniform DIF only (i.e., difference in discrimination parameter "a"), "both" for uniform and non-uniform DIF (i.e., difference in parameters "a" and "b"), or combination of parameters "a", "b", "c", and "d". Can be specified as a single value (for all items) or as an item-specific vector.

parameterization	character: parameterization of regression coefficients. Possible options are "classic" (IRT parameterization), "alternative" (default) and "logistic" (logistic regression). See Details .
outcome	character: name of outcome to be printed in formula. If not specified "y" is used.

Details

The unconstrained form of 4PL generalized logistic regression model for probability of correct answer (i.e., $y = 1$) is

$$P(y = 1) = (c + cDif * g) + (d + dDif * g - c - cDif * g) / (1 + \exp(-(a + aDif * g) * (x - b - bDif * g))),$$

where x is by default standardized total score (also called Z-score) and g is a group membership. Parameters a , b , c , and d are discrimination, difficulty, guessing, and inattention. Terms $aDif$, $bDif$, $cDif$, and $dDif$ then represent differences between two groups (reference and focal) in relevant parameters.

The `model` argument offers several predefined models. The options are as follows: Rasch for 1PL model with discrimination parameter fixed on value 1 for both groups, 1PL for 1PL model with discrimination parameter fixed for both groups, 2PL for logistic regression model, 3PLcg for 3PL model with fixed guessing for both groups, 3PLdg for 3PL model with fixed inattention for both groups, 3PLc (alternatively also 3PL) for 3PL regression model with guessing parameter, 3PLd for 3PL model with inattention parameter, 4PLcgdg for 4PL model with fixed guessing and inattention parameter for both groups, 4PLcgd (alternatively also 4PLd) for 4PL model with fixed guessing for both groups, 4PLcdg (alternatively also 4PLc) for 4PL model with fixed inattention for both groups, or 4PL for 4PL model.

Three possible parameterization can be specified in "parameterization" argument: "classic" returns IRT parameters of reference group and differences in these parameters between reference and focal group. "alternative" returns IRT parameters of reference group, the differences in parameters "a" and "b" between two groups and parameters "c" and "d" for focal group. "logistic" returns parameters in logistic regression parameterization.

Value

A list of two models. Both includes formula, parameters to be estimated and their lower and upper constraints.

genNLR	<i>Generates data set based on generalized logistic regression DIF and DDF models.</i>
--------	--

Description

Generates dichotomous, nominal, and ordinal data based on generalized logistic regression models for DIF and DDF detection.

Usage

```
genNLR(N = 1000, ratio = 1, itemtype = "dich", a, b, c, d, mu = 0, sigma = 1)
```

Arguments

N	numeric: number of rows representing respondents. (default is 1000).
ratio	numeric: ratio of respondents number in reference and focal group.
itemtype	character: type of items to be generated. Options are "dich" (default) for dichotomous item based on non-linear regression model for DIF detection (see difNLR for details), "nominal" for nominal items based on multinomial model for DDF detection (see ddfMLR for detail), and "ordinal" for ordinal data based on adjacent category logit model (for details see diFORD).
a	numeric: matrix representing discriminations with m rows (where m is number of items). Need to be provided. See Details .

b	numeric: numeric: matrix representing difficulties with m rows (where m is number of items). Need to be provided. See Details .
c	numeric: matrix representing guessings (lower asymptotes) with m rows (where m is number of items). Default is NULL. See Details .
d	numeric: matrix representing inattentions (upper asymptotes) with m rows (where m is number of items). Default is NULL. See Details .
mu	numeric: a mean vector of the underlying distribution. The first value corresponds to reference group, the second to focal group. Default is 0 value for both groups.
sigma	numeric: a standard deviation vector of the underlying distribution. The first value corresponds to reference group, the second to focal group. Default is 1 value for both groups.

Details

The a, b, c and d are numeric matrices with m rows (where m is number of items) representing parameters of regression models for DIF and DDF detection.

For option `itemtype = "dich"`, matrices should have two columns. The first column represents parameters of the reference group and the second of the focal group. In case that only one column is provided, parameters are set to be the same for both groups.

For options `itemtype = "nominal"` and `itemtype = "ordinal"`, matrices c and d are ignored. Matrices a and b contain parameters for distractors. For example, when item with 4 different choices is supposed to be generated, user provide matrices with 6 columns. First 3 columns correspond to distractors parameters for reference group and last three columns for focal group. The number of choices can differ for items. Matrices a and b need to consist of as many columns as is the maximum number of distractors. Items with less choices can contain NAs.

Value

A data frame containing N rows representing respondents and $m + 1$ columns representing m items. The last column is group membership variable with coding "0" for reference group and "1" for focal group.

```

Description

The GMAT is a generated dataset based on parameters from Graduate Management Admission Test (GMAT, Kingston et al., 1985). First two items were considered to function differently in uniform and non-uniform way respectively. The dataset represents responses of 2,000 subjects to multiple-choice test of 20 items. A correct answer is coded as 1 and incorrect answer as 0. The column `group` represents group membership, where 0 indicates reference group and 1 indicates focal group. Groups are the same size (i.e. 1,000 per group). The distributions of total scores (sum of correct answers) are the same for both reference and focal group (Martinkova et al., 2017). The column `criterion` represents generated continuous variable which is intended to be predicted by test.

Usage

```
data(GMAT)
```

Format

A GMAT data frame consists of 2,000 observations on the following 22 variables:

Item1-Item20 dichotomously scored items of the test

group group membership vector, "0" reference group, "1" focal group

criterion continuous criterion intended to be predicted by test

GMAT2test

Dataset based on GMAT.

Description

The GMAT2test is a generated dataset based on parameters from Graduate Management Admission Test (GMAT, Kingston et al., 1985). First two items were considered to function differently in uniform and non-uniform way respectively. The data set represents responses of 1,000 subjects to multiple-choice test of 20 items. Additionally, 4 possible answers on all items were generated, coded A, B, C, and D. The column group represents group membership, where 0 indicates reference group and 1 indicates focal group. Groups are the same size (i.e. 500 per group).

Usage

```
data(GMAT2test)
```

Format

A GMAT2test data frame consists of 1,000 observations on the following 21 variables:

Item1-Item20 nominal items of the test coded A, B, C, and D

group group membership vector, "0" reference group, "1" focal group

Correct answers are presented in [GMAT2key](#) data set.

logLik.ddfMLR	<i>Loglikelihood and information criteria for an object of "ddfMLR" class.</i>
---------------	--

Description

S3 methods for extracting loglikelihood, Akaike's information criterion (AIC) and Schwarz's Bayesian criterion (BIC) for an object of "ddfMLR" class.

Usage

```
## S3 method for class 'ddfMLR'
logLik(object, item = "all", ...)
```

```
## S3 method for class 'ddfMLR'
AIC(object, item = "all", ...)
```

```
## S3 method for class 'ddfMLR'
BIC(object, item = "all", ...)
```

Arguments

object	an object of "ddfMLR" class.
item	numeric or character: either character "all" to apply for all converged items (default), or a vector of item names (column names of Data), or item identifiers (integers specifying the column number).
...	other generic parameters for S3 methods.

BIC(x, item = 1)
logLik(x, item = 1)

## End(Not run)
```

logLik.difNLR

Loglikelihood and information criteria for an object of "difNLR" class.

Description

S3 methods for extracting loglikelihood, Akaike's information criterion (AIC) and Schwarz's Bayesian criterion (BIC) for an object of "difNLR" class.

Usage

```
## S3 method for class 'difNLR'
logLik(object, item = "all", ...)

## S3 method for class 'difNLR'
AIC(object, item = "all", ...)

## S3 method for class 'difNLR'
BIC(object, item = "all", ...)
```

Arguments

<code>object</code>	an object of "difNLR" class.
<code>item</code>	numeric or character: either character "all" to apply for all converged items (default), or a vector of item names (column names of <code>Data</code>), or item identifiers (integers specifying the column number).
<code>...</code>	other generic parameters for S3 methods.

 MLR

DDF likelihood ratio statistics based on multinomial log-linear regression model.

Description

Calculates DDF likelihood ratio statistics for nominal data based on multinomial log-linear model.

Usage

```
MLR(Data, group, key, type = "both", match = "zscore", anchor = 1:ncol(Data),
     p.adjust.method = "none", parametrization = "irt", alpha = 0.05)
```

Arguments

Data	data.frame or matrix: dataset which rows represent unscored examinee answers (nominal) and columns correspond to the items.
group	numeric: binary vector of group membership. "0" for reference group, "1" for focal group.
key	character: the answer key. Each element corresponds to the correct answer of one item.
type	character: type of DDF to be tested. Either "both" for uniform and non-uniform DDF (i.e., difference in parameters "a" and "b") (default), or "udif" for uniform DDF only (i.e., difference in difficulty parameter "b"), or "nudif" for non-uniform DDF only (i.e., difference in discrimination parameter "a"). Can be specified as a single value (for all items) or as an item-specific vector.
match	numeric or character: matching criterion to be used as an estimate of trait. Can be either "zscore" (default, standardized total score), "score" (total test score), or vector of the same length as number of observations in Data.
anchor	character or numeric: specification of DIF free items. A vector of item identifiers (integers specifying the column number) specifying which items are currently considered as anchor (DIF free) items. Argument is ignored if match is not "zscore" or "score".
p.adjust.method	character: method for multiple comparison correction. Possible values are "holm", "hochberg", "hommel", "bonferroni", "BH", "BY", "fdr", and "none" (default). For more details see p.adjust .
parametrization	character: parametrization of regression coefficients. Possible options are "irt" for difficulty-discrimination parametrization (default) and "classic" for intercept-slope parametrization. See Details .
alpha	numeric: significance level (default is 0.05).

Details

Calculates DDF likelihood ratio statistics based on multinomial log-linear model. Probability of selection the k -th category (distractor) is

$$P(y = k) = \exp((a_k + a_k Dif * g) * (x - b_k - b_k Dif * g)) / (1 + \sum \exp((a_l + a_l Dif * g) * (x - b_l - b_l Dif * g))),$$

where x is by default standardized total score (also called Z-score) and g is a group membership. Parameters a_k and b_k are discrimination and difficulty for the k -th category. Terms $a_k Dif$ and $b_k Dif$ then represent differences between two groups (reference and focal) in relevant parameters. Probability of correct answer (specified in argument key) is

$$P(y = k) = 1 / (1 + \sum \exp((a_l + a_l Dif * g) * (x - b_l - b_l Dif * g))).$$

Parameters are estimated via neural networks. For more details see [multinom](#).

Argument `parametrization` is a character which specifies parametrization of regression parameters. Default option is `"irt"` which returns IRT parametrization (difficulty-discrimination, see above). Option `"classic"` returns intercept-slope parametrization with effect of group membership and interaction with matching criterion, i.e. $b_0k + b_1k * x + b_2k * g + b_3k * x * g$ instead of $(a_k + a_k Dif * g) * (x - b_k - b_k Dif * g)$.

Value

A list with the following arguments:

`sval` the values of likelihood ratio test statistics.

`pval` the p-values by likelihood ratio test.

`adj.pval` the adjusted p-values by likelihood ratio test using `p.adjust.method`.

`df` the degrees of freedom of likelihood ratio test.

`par.m0` the estimates of null model.

`par.m1` the estimates of alternative model.

`se.m0` standard errors of parameters in null model.

`se.m1` standard errors of parameters in alternative model.

`ll.m0` log-likelihood of m0 model.

`ll.m1` log-likelihood of m1 model.

`AIC.m0` AIC of m0 model.

`AIC.m1` AIC of m1 model.

`BIC.m0` BIC of m0 model.

`BIC.m1` BIC of m1 model.

MSATB

Dichotomous dataset of Medical School Admission Test in Biology.

Description

The MSATB dataset consists of the responses of 1,407 subjects (484 males, 923 females) to admission test to medical school in the Czech republic. It contains 20 selected items from original test while first item was previously detected as differently functioning (Vlckova, 2014). A correct answer is coded as 1 and incorrect answer as 0. The column gender represents gender of students, where 0 indicates males (reference group) and 1 indicates females (focal group).

Usage

```
data(MSATB)
```

Format

A MSATB data frame consists of 1,407 observations on the following 21 variables:

Item dichotomously scored items of the test

gender gender of respondents, "0" males, "1" females

MSATBtest

Dataset of School Admission Test in Biology.

Description

The MSATBtest dataset consists of the responses of 1,407 subjects (484 males, 923 females) to multiple-choice admission test to medical school in the Czech republic. It contains 20 selected items from original test while first item was previously detected as differently functioning (Vlckova, 2014). Possible answers were A, B, C, and D, while any combination of these can be correct. The column gender represents gender of students, where 0 indicates males (reference group) and 1 indicates females (focal group).

Usage

```
data(MSATBtest)
```

Format

A MSATBtest data frame consists of 1,407 observations on the following 21 variables:

Item nominal items of the test

gender gender of respondents, "0" males, "1" females

NLR

DIF statistics based on non-linear regression model.

Description

Calculates either DIF likelihood ratio statistics or F statistics for dichotomous data based on non-linear regression model (generalized logistic regression model).

Usage

```
NLR(Data, group, model, constraints = NULL, type = "all", method = "nls",
     match = "zscore", anchor = 1:ncol(Data), start, p.adjust.method = "none", test = "LR",
     alpha = 0.05, initboot = TRUE, nrBo = 20, sandwich = FALSE)
```

Arguments

Data	data.frame or matrix: dataset which rows represent scored examinee answers ("1" correct, "0" incorrect) and columns correspond to the items.
group	numeric: binary vector of group membership. "0" for reference group, "1" for focal group.
model	character: generalized logistic regression model to be fitted. See Details .
constraints	character: which parameters should be the same for both groups. Possible values are any combinations of parameters "a", "b", "c", and "d". Default value is NULL. See Details .
type	character: type of DIF to be tested. Possible values are "all" for detecting difference in any parameter (default), "udif" for uniform DIF only (i.e., difference in difficulty parameter "b"), "nudif" for non-uniform DIF only (i.e., difference in discrimination parameter "a"), "both" for uniform and non-uniform DIF (i.e., difference in parameters "a" and "b"), or combination of parameters "a", "b", "c", and "d". Can be specified as a single value (for all items) or as an item-specific vector.
method	character: method used to estimate parameters. The options are "nls" for non-linear least squares (default) and "likelihood" for maximum likelihood method.

match	character or numeric: matching criterion to be used as estimate of trait. Can be either "zscore" (default, standardized total score), "score" (total test score), or numeric vector of the same length as number of observations in Data.
anchor	character or numeric: specification of DIF free items. A vector of item identifiers (integers specifying the column number) specifying which items are currently considered as anchor (DIF free) items. Argument is ignored if match is not "zscore" or "score".
start	numeric: initial values for estimation of parameters. If not specified, starting values are calculated with <code>startNLR</code> function. Otherwise, list with as many elements as number of items. Each element is a named numeric vector of length 8 representing initial values for parameter estimation. Specifically, parameters "a", "b", "c", and "d" are initial values for discrimination, difficulty, guessing, and inattention for reference group. Parameters "aDif", "bDif", "cDif", and "dDif" are then differences in these parameters between reference and focal group.
p.adjust.method	character: method for multiple comparison correction. Possible values are "holm", "hochberg", "hommel", "bonferroni", "BH", "BY", "fdr", and "none" (default). For more details see p.adjust .
test	character: test to be performed for DIF detection. Can be either "LR" for likelihood ratio test of a submodel (default), "W" for Wald test, or "F" for F-test of a submodel.
alpha	numeric: significance level (default is 0.05).
initboot	logical: in case of convergence issues, should be starting values re-calculated based on bootstrapped samples? (default is TRUE; newly calculated initial values are applied only to items/models with convergence issues).
nrBo	numeric: the maximal number of iterations for calculation of starting values using bootstrapped samples (default is 20).
sandwich	logical: should be sandwich estimator used for covariance matrix of parameters when using method = "nlS"? Default is FALSE.

Details

Calculation of the test statistics using DIF detection procedure based on non-linear regression (extension of logistic regression procedure; Swaminathan and Rogers, 1990; Drabinova and Martinkova, 2017).

The unconstrained form of 4PL generalized logistic regression model for probability of correct answer (i.e., $y = 1$) is

$$P(y = 1) = (c + cDif * g) + (d + dDif * g - c - cDif * g) / (1 + \exp(-(a + aDif * g) * (x - b - bDif * g))),$$

where x is by default standardized total score (also called Z-score) and g is a group membership. Parameters a , b , c , and d are discrimination, difficulty, guessing, and inattention. Terms $aDif$, $bDif$, $cDif$, and $dDif$ then represent differences between two groups (reference and focal) in relevant parameters.

This 4PL model can be further constrained by `model` and `constraints` arguments. The arguments `model` and `constraints` can be also combined. Both arguments can be specified as a single value (for all items) or as an item-specific vector (where each element correspond to one item).

The `model` argument offers several predefined models. The options are as follows: `Rasch` for 1PL model with discrimination parameter fixed on value 1 for both groups, `1PL` for 1PL model with discrimination parameter fixed for both groups, `2PL` for logistic regression model, `3PLcg` for 3PL model with fixed guessing for both groups, `3PLdg` for 3PL model with fixed inattention for both groups, `3PLc` (alternatively also `3PL`) for 3PL regression model with guessing parameter, `3PLd` for 3PL model with inattention parameter, `4PLcgdg` for 4PL model with fixed guessing and inattention parameter for both groups, `4PLcgd` (alternatively also `4PLd`) for 4PL model with fixed guessing for both groups, `4PLcdg` (alternatively also `4PLc`) for 4PL model with fixed inattention for both groups, or `4PL` for 4PL model.

The `model` can be specified in more detail with `constraints` argument which specifies what parameters should be fixed for both groups. For example, choice `"ad"` means that discrimination (parameter `"a"`) and inattention (parameter `"d"`) are fixed for both groups and other parameters (`"b"` and `"c"`) are not. The `NA` value for `constraints` means no constraints.

In case that model considers difference in guessing or inattention parameter, the different parameterization is used and parameters with standard errors are re-calculated by delta method.

Value

A list with the following arguments:

`Sval` the values of test statistics.

`pval` the p-values by test.

`adjusted.pval` adjusted p-values by `p.adjust.method`.

`df` the degrees of freedom of test.

`test` used test.

`par.m0` the matrix of estimated item parameters for `m0` model.

`se.m0` the matrix of standard errors of item parameters for `m0` model.

`cov.m0` list of covariance matrices of item parameters for `m0` model.

`par.m1` the matrix of estimated item parameters for `m1` model.

`se.m1` the matrix of standard errors of item parameters for `m1` model.

`cov.m1` list of covariance matrices of item parameters for `m1` model.

`conv.fail` numeric: number of convergence issues.

`conv.fail.which` the indicators of the items which did not converge.

`ll.m0` log-likelihood of `m0` model.

`ll.m1` log-likelihood of `m1` model.

`startBo0` the binary matrix. Columns represents iterations of initial values re-calculations, rows represents items. The value of 0 means no convergence issue in `m0` model, 1 means convergence issue in `m0` model.

`startBo1` the binary matrix. Columns represents iterations of initial values re-calculations, rows represents items. The value of 0 means no convergence issue in `m1` model, 1 means convergence issue in `m1` model.

ORD

DIF likelihood ratio statistics for ordinal data.

Description

Calculates DIF likelihood ratio statistics for ordinal data based either on adjacent category logit regression model or on cumulative logit regression model.

Usage

```

ORD(Data, group, model = "adjacent", type = "both", match = "zscore",
     anchor = 1:ncol(Data), p.adjust.method = "none", parametrization = "irt",
     alpha = 0.05)

```

Arguments

Data	data.frame or matrix: dataset which rows represent ordinaly scored examinee answers and columns correspond to the items.
group	numeric: binary vector of group membership. "0" for reference group, "1" for focal group.
model	character: logistic regression model for ordinal data (either "adjacent" (default) or "cumulative"). See Details .
type	character: type of DIF to be tested. Either "both" for uniform and non-uniform DIF (i.e., difference in parameters "a" and "b") (default), or "udif" for uniform DIF only (i.e., difference in difficulty parameter "b"), or "nudif" for non-uniform DIF only (i.e., difference in discrimination parameter "a"). Can be specified as a single value (for all items) or as an item-specific vector.
match	numeric or character: matching criterion to be used as an estimate of trait. Can be either "zscore" (default, standardized total score), "score" (total test score), or vector of the same length as number of observations in Data.

anchor	character or numeric: specification of DIF free items. A vector of item identifiers (integers specifying the column number) specifying which items are currently considered as anchor (DIF free) items. Argument is ignored if match is not "zscore" or "score".
p.adjust.method	character: method for multiple comparison correction. Possible values are "holm", "hochberg", "hommel", "bonferroni", "BH", "BY", "fdr", and "none" (default). For more details see p.adjust .
parametrization	character: parametrization of regression coefficients. Possible options are "irt" for difficulty-discrimination parametrization (default) and "classic" for intercept-slope parametrization. See Details .
alpha	numeric: significance level (default is 0.05).

Details

Calculates DIF likelihood ratio statistics based either on adjacent category logit model or on cumulative logit model for ordinal data.

Using adjacent category logit model, logarithm of ratio of probabilities of two adjacent categories is

$$\log(P(y = k)/P(y = k - 1)) = (a + a_{Dif} * g) * (x - b_k - b_k_{Dif} * g),$$

where x is by default standardized total score (also called Z-score) and g is a group membership. Parameter a is a discrimination of the item and parameter b_k is difficulty for the k -th category of the item. Terms a_{Dif} and b_k_{Dif} then represent differences between two groups (reference and focal) in relevant parameters.

Using cumulative logit model, probability of gaining at least k points is given by 2PL model, i.e.,

$$P(y \geq k) = \exp((a + a_{Dif} * g) * (x - b_k - b_k_{Dif} * g)) / (1 + \exp((a + a_{Dif} * g) * (x - b_k - b_k_{Dif} * g))).$$

The category probability (i.e., probability of gaining exactly k points) is then $P(Y = k) = P(Y \geq k) - P(Y \geq k + 1)$.

Both models are estimated by iteratively reweighted least squares. For more details see [vglm](#).

Argument `parametrization` is a character which specifies parametrization of regression parameters. Default option is "irt" which returns IRT parametrization (difficulty-discrimination, see above). Option "classic" returns intercept-slope parametrization with effect of group membership and interaction with matching criterion, i.e. $b_0k + b_1 * x + b_2k * g + b_3 * x * g$ instead of $(a + a_{Dif} * g) * (x - b_k - b_k_{Dif} * g)$.

Value

A list with the following arguments:

`sval` the values of likelihood ratio test statistics.

`pval` the p-values by likelihood ratio test.

`adj.pval` the adjusted p-values by likelihood ratio test using `p.adjust.method`.

`df` the degrees of freedom of likelihood ratio test.

par.m0 the estimates of null model.
par.m1 the estimates of alternative model.
se.m0 standard errors of parameters in null model.
se.m1 standard errors of parameters in alternative model.
ll.m0 log-likelihood of null model.
ll.m1 log-likelihood of alternative model.
AIC.m0 AIC of null model.
AIC.m1 AIC of alternative model.
BIC.m0 BIC of null model.
BIC.m1 BIC of alternative model.

plot.ddfMLR *ICC plots for an object of "ddfMLR" class.*

Description

Plot method for an object of "ddfMLR" class using **ggplot2**.

The characteristic curves for an item specified in `item` argument are plotted. Plotted curves represent the best model.

Usage

```
## S3 method for class 'ddfMLR'
plot(x, item = "all", group.names, ...)
```

Arguments

<code>x</code>	an object of "ddfMLR" class.
<code>item</code>	numeric or character: either character "all" to apply for all items (default), or a vector of item names (column names of <code>Data</code>), or item identifiers (integers specifying the column number).
<code>group.names</code>	character: names of reference and focal group.
<code>...</code>	other generic parameters for <code>plot()</code> function.

Value

Returns list of objects of class "ggplot".

```

plot.difNLR

ICC and test statistics plots for an object of "difNLR" class.

Description

Plot method for an object of "difNLR" class using **ggplot2**.

Two types of plots are available. The first one is obtained by setting `plot.type = "cc"` (default). The characteristic curves for an item specified in `item` argument are plotted. Plotted curves represent the best model.

The second plot is obtained by setting `plot.type = "stat"`. The test statistics (either LR-test, or F-test, depends on argument `test`) are displayed on the Y axis, for each converged item. The detection threshold is displayed by a horizontal line and items detected as DIF are printed with the red color. Only parameters `size` and `title` are used.

Usage

```
## S3 method for class 'difNLR'
plot(
  x,
  plot.type = "cc",
  item = "all",
  group.names,
  draw.empirical = TRUE,
  draw.CI = FALSE,
  ...
)
```

Arguments

<code>x</code>	an object of "difNLR" class.
<code>plot.type</code>	character: type of plot to be plotted (either "cc" for characteristic curve (default), or "stat" for test statistics).
<code>item</code>	numeric or character: either character "all" to apply for all converged items (default), or a vector of item names (column names of Data), or item identifiers (integers specifying the column number).
<code>group.names</code>	character: names of reference and focal group.
<code>draw.empirical</code>	logical: should empirical probabilities be plotted as points? Default value is TRUE.
<code>draw.CI</code>	logical: should confidence intervals for predicted values be plotted? Default value is FALSE.
<code>...</code>	other generic parameters for plot() function.

Value

For an option `plot.type = "stat"`, returns object of class "ggplot". In case of `plot.type = "cc"`, returns list of objects of class "ggplot".

Outputs can be edited and modified as standard "ggplot" object including colours, titles, shapes or linetypes.

Note that option `draw.CI = TRUE` returns confidence intervals for predicted values as calculated by [predict.difNLR](#). Confidence intervals may overlap even in case that item functions differently.

plot.difORD *ICC plots for an object of "difORD" class.*

Description

Plot method for an object of "difORD" class using **ggplot2**.

The characteristic curves (category probabilities) for an item specified in `item` argument are plotted. Plotted curves represent the best model. For cumulative logit model, also cumulative probabilities may be plotted.

Usage

```
## S3 method for class 'difORD'  
plot(x, item = "all", plot.type, group.names, ...)
```

Arguments

<code>x</code>	an object of "difORD" class.
<code>item</code>	numeric or character: either character "all" to apply for all converged items (default), or a vector of item names (column names of Data), or item identifiers (integers specifying the column number).
<code>plot.type</code>	character: which plot should be displayed for cumulative logit regression model. Either "category" (default) for category probabilities or "cumulative" for cumulative probabilities.
<code>group.names</code>	character: names of reference and focal group.
<code>...</code>	other generic parameters for <code>plot()</code> function.

Value

Returns list of objects of class "ggplot".

```

predict.difNLR

Predicted values for an object of "difNLR" class.

Description

S3 method for predictions from the model used in the object of "difNLR" class.

Usage

```
## S3 method for class 'difNLR'
predict(
  object,
  item = "all",
  match,
  group,
  interval = "none",
  level = 0.95,
  ...
)
```

Arguments

object	an object of "difNLR" class.
item	numeric or character: either character "all" to apply for all converged items (default), or a vector of item names (column names of Data), or item identifiers (integers specifying the column number).
match	numeric: matching criterion for new observations.

group	numeric: group membership for new observations.
interval	character: type of interval calculation, either "none" (default) or "confidence" for confidence interval.
level	numeric: confidence level.
...	other generic parameters for predict() function.

[difNLR](#) for DIF detection among binary data using generalized logistic regression model.
[predict](#) for generic function for prediction.

Examples

```
## Not run:
# Loading data based on GMAT
data(GMAT)

Data <- GMAT[, 1:20]
group <- GMAT[, "group"]

# Testing both DIF effects using likelihood-ratio test and
# 3PL model with fixed guessing for groups
```

```
(x <- difNLR(Data, group, focal.name = 1, model = "3PLcg"))

# Predicted values
summary(predict(x))
predict(x, item = 1)
predict(x, item = "Item1")

# Predicted values for new observations - average score
predict(x, item = 1, match = 0, group = 0) # reference group
predict(x, item = 1, match = 0, group = 1) # focal group

# Predicted values for new observations - various z-scores and groups
new.match <- rep(c(-1, 0, 1), 2)
new.group <- rep(c(0, 1), each = 3)
predict(x, item = 1, match = new.match, group = new.group)

# Predicted values for new observations with confidence intervals
predict(x, item = 1, match = new.match, group = new.group, interval = "confidence")
predict(x, item = c(2, 4), match = new.match, group = new.group, interval = "confidence")

## End(Not run)
```

startNLR

Calculates starting values for non-linear regression DIF models.

Description

Calculates starting values for difNLR() function based on linear approximation.

Usage

```
startNLR(Data, group, model, match = "zscore", parameterization = "alternative",
          simplify = FALSE)
```

Arguments

Data	Data data.frame or matrix: dataset which rows represent scored examinee answers ("1" correct, "0" incorrect) and columns correspond to the items.
group	numeric: binary vector of group membership. "0" for reference group, "1" for focal group.
model	character: generalized logistic regression model for which starting values should be estimated. See Details .
match	character or numeric: matching criterion to be used as estimate of trait. Can be either "zscore" (default, standardized total score), "score" (total test score), or numeric vector of the same length as number of observations in Data.

parameterization	character: parameterization of regression coefficients. Possible options are "classic" (IRT parameterization), "alternative" (default) and "logistic" (logistic regression). See Details .
simplify	logical: should initial values be simplified into the matrix? This is only applicable when parameterization is the same for all items.

Details

The unconstrained form of 4PL generalized logistic regression model for probability of correct answer (i.e., $y = 1$) is

$$P(y = 1) = (c + cDif * g) + (d + dDif * g - c - cDif * g) / (1 + \exp(-(a + aDif * g) * (x - b - bDif * g))),$$

where x is by default standardized total score (also called Z-score) and g is a group membership. Parameters a , b , c , and d are discrimination, difficulty, guessing, and inattention. Terms $aDif$, $bDif$, $cDif$, and $dDif$ then represent differences between two groups (reference and focal) in relevant parameters.

The `model` argument offers several predefined models. The options are as follows: Rasch for 1PL model with discrimination parameter fixed on value 1 for both groups, 1PL for 1PL model with discrimination parameter fixed for both groups, 2PL for logistic regression model, 3PLcg for 3PL model with fixed guessing for both groups, 3PLdg for 3PL model with fixed inattention for both groups, 3PLc (alternatively also 3PL) for 3PL regression model with guessing parameter, 3PLd for 3PL model with inattention parameter, 4PLcgdg for 4PL model with fixed guessing and inattention parameter for both groups, 4PLcgd (alternatively also 4PLd) for 4PL model with fixed guessing for both groups, 4PLcdg (alternatively also 4PLc) for 4PL model with fixed inattention for both groups, or 4PL for 4PL model.

Three possible parameterization can be specified in "parameterization" argument: "classic" returns IRT parameters of reference group and differences in these parameters between reference and focal group. "alternative" returns IRT parameters of reference group, the differences in parameters "a" and "b" between two groups and parameters "c" and "d" for focal group. "logistic" returns parameters in logistic regression parameterization.

Value

A list containing elements representing items. Each element is a named numeric vector of length 8 with initial values for generalized logistic regression model.
