Package ‘dm’

November 21, 2021

Title  Relational Data Models

Version  0.2.6

Date  2021-11-21

Description  Provides tools for working with multiple related tables, stored as data frames or in a relational database. Multiple tables (data and metadata) are stored in a compound object, which can then be manipulated with a pipe-friendly syntax.

License  MIT + file LICENSE

check_key

Description

check_key() accepts a data frame and, optionally, columns. It throws an error if the specified columns are NOT a unique key of the data frame. If the columns given in the ellipsis ARE a key, the data frame itself is returned silently, so that it can be used for piping.

Usage

check_key(.data, ...)

Arguments

.data The data frame whose columns should be tested for key properties.

... The names of the columns to be checked.

One or more unquoted expressions separated by commas. Variable names can be treated as if they were positions, so you can use expressions like x:y to select ranges of variables.

The arguments in ... are automatically quoted and evaluated in a context where column names represent column positions. They also support unquoting and splicing. See vignette("programming") for an introduction to these concepts.
check_set_equality

See select helpers for more details and examples about tidyselect helpers such as starts_with(), everything(), ...

Value

Returns .data, invisibly, if the check is passed. Otherwise an error is thrown and the reason for it is explained.

Examples

data <- tibble(a = c(1, 2, 1), b = c(1, 4, 1), c = c(5, 6, 7))
# this is failing:
try(check_key(data, a, b))

# this is passing:
check_key(data, a, c)

check_set_equality Check column values for set equality

Description

check_set_equality() is a wrapper of check_subset(). It tests if one value set is a subset of another and vice versa, i.e., if both sets are the same. If not, it throws an error.

Usage

check_set_equality(t1, c1, t2, c2)

Arguments

t1 The data frame that contains the columns c1.
c1 The columns of t1 that should only contain values that are also present in columns c2 of data frame t2. Multiple columns can be chosen using c(col1, col2).
t2 The data frame that contains the columns c2.
c2 The columns of t2 that should only contain values that are also present in columns c1 of data frame t1. Multiple columns can be chosen using c(col1, col2).

Value

Returns t1, invisibly, if the check is passed. Otherwise an error is thrown and the reason for it is explained.
check_subset

Examples

```r
data_1 <- tibble::tibble(a = c(1, 2, 1), b = c(1, 4, 1), c = c(5, 6, 7))
data_2 <- tibble::tibble(a = c(1, 2, 3), b = c(4, 5, 6), c = c(7, 8, 9))
# this is failing:
try(check_set_equality(data_1, a, data_2, a))

data_3 <- tibble::tibble(a = c(2, 1, 2), b = c(4, 5, 6), c = c(7, 8, 9))
# this is passing:
check_set_equality(data_1, a, data_3, a)
```

cHECK COLUMN VALUES FOR SUBSET

Description

check_subset() tests if the values of the chosen columns c1 of data frame t1 are a subset of the values of columns c2 of data frame t2.

Usage

```r
check_subset(t1, c1, t2, c2)
```

Arguments

- **t1**: The data frame that contains the columns c1.
- **c1**: The columns of t1 that should only contain values that are also present in columns c2 of data frame t2. Multiple columns can be chosen using `c(col1,col2)`.
- **t2**: The data frame that contains the columns c2.
- **c2**: The columns of the second data frame which have to contain all values of c1 to avoid an error. Multiple columns can be chosen using `c(col1,col2)`.

Value

Returns t1, invisibly, if the check is passed. Otherwise an error is thrown and the reason for it is explained.

Examples

```r
data_1 <- tibble::tibble(a = c(1, 2, 1), b = c(1, 4, 1), c = c(5, 6, 7))
data_2 <- tibble::tibble(a = c(1, 2, 3), b = c(4, 5, 6), c = c(7, 8, 9))
# this is passing:
check_subset(data_1, a, data_2, a)

# this is failing:
try(check_subset(data_2, a, data_1, a))
```
Copy data model to data source

copy_dm_to

description

copy_dm_to() takes a dplyr::src_dbi object or a DBI::DBIConnection object as its first argument and a dm object as its second argument. The latter is copied to the former. The default is to create temporary tables, set temporary = FALSE to create permanent tables. Unless set_key_constraints is FALSE, primary key constraints are set on all databases, and in addition foreign key constraints are set on MSSQL and Postgres databases.

Usage

copy_dm_to(
    dest,
    dm,
    ...,
    types = NULL,
    overwrite = NULL,
    indexes = NULL,
    unique_indexes = NULL,
    set_key_constraints = TRUE,
    unique_table_names = NULL,
    table_names = NULL,
    temporary = TRUE,
    schema = NULL,
    progress = NA,
    copy_to = NULL
)

Arguments

dest An object of class "src" or "DBIConnection".
dm A dm object.
... Passed on to dplyr::copy_to() or to the function specified by the copy_to argument.
overwrite, types, indexes, unique_indexes Must remain NULL.
set_key_constraints If TRUE will mirror dm primary and foreign key constraints on a database and create unique indexes. Set to FALSE if your data model currently does not satisfy primary or foreign key constraints.
unique_table_names Deprecated.
**copy_dm_to**

**table_names** Desired names for the tables on dest; the names within the dm remain unchanged. Can be NULL, a named character vector, a function or a one-sided formula.

If left NULL (default), the names will be determined automatically depending on the temporary argument:

1. temporary = TRUE (default): unique table names based on the names of the tables in the dm are created.
2. temporary = FALSE: the table names in the dm are used as names for the tables on dest.

If a function or one-sided formula, table_names is converted to a function using `rlang::as_function()`. This function is called with the unquoted table names of the dm object as the only argument. The output of this function is processed by `DBI::dbQuoteIdentifier()`, that result should be a vector of identifiers of the same length as the original table names.

Use a variant of `table_names = ~ DBI::SQL(paste0("schema_name",".",.x))` to specify the same schema for all tables. Use `table_names = identity` with temporary = TRUE to avoid giving temporary tables unique names.

If a named character vector, the names of this vector need to correspond to the table names in the dm, and its values are the desired names on dest. The value is processed by `DBI::dbQuoteIdentifier()`, that result should be a vector of identifiers of the same length as the original table names.

Use qualified names corresponding to your database’s syntax to specify e.g. database and schema for your tables.

**temporary** If TRUE, only temporary tables will be created. These tables will vanish when disconnecting from the database.

**schema** Name of schema to copy the dm to. If schema is provided, an error will be thrown if temporary = FALSE or table_names is not NULL.

Not all DBMS are supported.

**progress** Whether to display a progress bar, if NA (the default) hide in non-interactive mode, show in interactive mode. Requires the 'progress' package.

**copy_to** By default, `dplyr::copy_to()` is called to upload the individual tables to the target data source. This argument allows overriding the standard behavior in cases when the default does not work as expected, such as spatial data frames or other tables with special data types. If not NULL, this argument is processed with `rlang::as_function()`.

**Details**

No tables will be overwritten; passing `overwrite = TRUE` to the function will give an error. Types are determined separately for each table, setting the types argument will also throw an error. The arguments are included in the signature to avoid passing them via the ... ellipsis.

**Value**

A dm object on the given src with the same table names as the input dm.
Examples

con <- DBI::dbConnect(RSQLite::SQLite())

# Copy to temporary tables, unique table names by default:
temp_dm <- copy_dm_to(
  con,
  dm_nycflights13(),
  set_key_constraints = FALSE
)

# Persist, explicitly specify table names:
persistent_dm <- copy_dm_to(
  con,
  dm_nycflights13(),
  temporary = FALSE,
  table_names = ~ paste0("flights_", .x)
)
dbplyr::remote_name(persistent_dm$planes)

DBI::dbDisconnect(con)

db_schema_create() creates a schema on the database.

Description

[Experimental]

Arguments

con An object of class "src" or "DBIConnection".
schema Class character or SQL (cf. Details), name of the schema
... Passed on to the individual methods.

Details

Methods are not available for all DBMS.
An error is thrown if a schema of that name already exists.
The argument schema (and dbname for MSSQL) can be provided as SQL objects. Keep in mind, that in this case it is assumed that they are already correctly quoted as identifiers using DBI::dbQuoteIdentifier().

Additional arguments are:
• dbname: supported for MSSQL. Create a schema in a different database on the connected MSSQL-server; default: database addressed by con.

Value

NULL invisibly.

See Also

Other schema handling functions: \texttt{db_schema_drop()}, \texttt{db_schema_exists()}, \texttt{db_schema_list()}

---

\textbf{db_schema_drop} \hspace{5em} \textit{Remove a schema from a database}

---

\textbf{Description}

\textbf{[Experimental]}
\texttt{db_schema_drop()} deletes a schema from the database. For certain DBMS it is possible to force the removal of a non-empty schema, see below.

\textbf{Usage}

\texttt{db_schema_drop(con, schema, force = FALSE, ...)}

\textbf{Arguments}

\begin{itemize}
  \item \texttt{con} \hspace{1em} An object of class "src" or "DBIConnection".
  \item \texttt{schema} \hspace{1em} Class character or SQL (cf. Details), name of the schema
  \item \texttt{force} \hspace{1em} Boolean, default FALSE. Set to TRUE to drop a schema and all objects it contains at once. Currently only supported for Postgres.
  \item \ldots \hspace{1em} Passed on to the individual methods.
\end{itemize}

\textbf{Details}

Methods are not available for all DBMS.

An error is thrown if no schema of that name exists.

The argument schema (and dbname for MSSQL) can be provided as SQL objects. Keep in mind, that in this case it is assumed that they are already correctly quoted as identifiers.

Additional arguments are:

\begin{itemize}
  \item dbname: supported for MSSQL. Remove a schema from a different database on the connected MSSQL-server; default: database addressed by con.
\end{itemize}

\textbf{Value}

NULL invisibly.
**db_schema_exists**

**See Also**

Other schema handling functions: `db_schema_create()`, `db_schema_exists()`, `db_schema_list()`

---

**db_schema_exists**  
*Check for existence of a schema on a database*

---

**Description**

[Experimental]

`db_schema_exists()` checks, if a schema exists on the database.

**Usage**

`db_schema_exists(con, schema, ...)`

**Arguments**

- `con`  
  An object of class "src" or "DBIConnection".

- `schema`  
  Class character or SQL, name of the schema

- `...`  
  Passed on to the individual methods.

**Details**

Methods are not available for all DBMS.

Additional arguments are:

- `dbname`: supported for MSSQL. Check if a schema exists on a different database on the connected MSSQL-server; default: database addressed by `con`.

**Value**

A boolean: TRUE if schema exists, FALSE otherwise.

**See Also**

Other schema handling functions: `db_schema_create()`, `db_schema_drop()`, `db_schema_list()`
**db_schema_list**  
*List schemas on a database*

**Description**

[Experimental]

`db_schema_list()` lists the available schemas on the database.

**Usage**

`db_schema_list(con, include_default = TRUE, ...)`

**Arguments**

- `con`  
  An object of class "src" or "DBIConnection".

- `include_default`  
  Boolean, if `TRUE` (default), also the default schema on the database is included in the result

- `...`  
  Passed on to the individual methods.

**Details**

Methods are not available for all DBMS.

Additional arguments are:

- `dbname`: supported for MSSQL. List schemas on a different database on the connected MSSQL-server; default: database addressed by `con`.

**Value**

A tibble with the following columns:

- `schema_name`: the names of the schemas,
- `schema_owner`: the schema owner names.

**See Also**

Other schema handling functions: `db_schema_create()`, `db_schema_drop()`, `db_schema_exists()`
decompose_table  

Decompose a table into two linked tables

Description

[Questioning]
Perform table surgery by extracting a 'parent table' from a table, linking the original table and the new table by a key, and returning both tables.

decompose_table() accepts a data frame, a name for the 'ID column' that will be newly created, and the names of the columns that will be extracted into the new data frame.

It creates a 'parent table', which consists of the columns specified in the ellipsis, and a new 'ID column'. Then it removes those columns from the original table, which is now called the 'child table, and adds the 'ID column'.

Usage

decompose_table(.data, new_id_column, ...)

Arguments

.data  
Data frame from which columns … are to be extracted.

new_id_column  
Name of the identifier column (primary key column) for the parent table. A column of this name is also added in 'child table'.

...  
The columns to be extracted from the .data.

One or more unquoted expressions separated by commas. You can treat variable names as if they were positions, so you can use expressions like x:y to select ranges of variables.

The arguments in ... are automatically quoted and evaluated in a context where column names represent column positions. They also support unquoting and splicing. See vignette("programming") for an introduction to those concepts.

See select helpers for more details, and the examples about tidyselect helpers, such as starts_with(), everything(), ...

Value

A named list of length two:

- entry "child_table": the child table with column new_id_column referring to the same column in parent_table,
- entry "parent_table": the "lookup table" for child_table.

Life cycle

This function is marked "questioning" because it feels more useful when applied to a table in a dm object.
See Also

Other table surgery functions: `reunite_parent_child()`

Examples

```r
decomposed_table <- decompose_table(mtcars, new_id, am, gear, carb)
decomposed_table$child_table
decomposed_table$parent_table
```

**Description**

The `dm` class holds a list of tables and their relationships. It is inspired by `datamodelr`, and extends the idea by offering operations to access the data in the tables.

`dm()` creates a `dm` object from `tbl` objects (tibbles or lazy data objects).

`new_dm()` is a low-level constructor that creates a new `dm` object.

- If called without arguments, it will create an empty `dm`.
- If called with arguments, no validation checks will be made to ascertain that the inputs are of the expected class and internally consistent; use `validate_dm()` to double-check the returned object.

`dm_get_con()` returns the DBI connection for a `dm` object. This works only if the tables are stored on a database, otherwise an error is thrown.

`dm_get_tables()` returns a named list of `dplyr` `tbl` objects of a `dm` object. Filtering expressions are NOT evaluated at this stage. To get a filtered table, use `dm_apply_filters_to_tbl()`, to apply filters to all tables use `dm_apply_filters()`

`is_dm()` returns `TRUE` if the input is of class `dm`.

`as_dm()` coerces objects to the `dm` class

`validate_dm()` checks the internal consistency of a `dm` object.

**Usage**

```r
dm(..., .name_repair = c("check_unique", "unique", "universal", "minimal"))

new_dm(tables = list())

dm_get_con()

dm_get_tables()

is_dm()

as_dm()

validate_dm()
```
Arguments

... Tables to add to the dm object. If no names are provided, the tables are auto-named.
.name_repair Options for name repair. Forwarded as repair to \texttt{vctrs::vec\_as\_names()}.
tables A named list of the tables (tibble-objects, not names), to be included in the dm object.
\textbf{x} An object.

Details

All lazy tables in a dm object must be stored on the same database server and accessed through the same connection.

Value

For \texttt{dm()}, \texttt{new\_dm()}, \texttt{as\_dm()}: A dm object.
For \texttt{dm\_get\_con():} The \texttt{DBI::DBIConnection} for dm objects.
For \texttt{dm\_get\_tables():} A named list with the tables constituting the dm.
For \texttt{is\_dm():} Boolean, is this object a dm.
For \texttt{validate\_dm():} Returns the dm, invisibly, after finishing all checks.

See Also

- \texttt{dm\_from\_src()} for connecting to all tables in a database and importing the primary and foreign keys
- \texttt{dm\_add\_pk()} and \texttt{dm\_add\_fk()} for adding primary and foreign keys
- \texttt{copy\_dm\_to()} for DB interaction
- \texttt{dm\_draw()} for visualization
- \texttt{dm\_join\_to\_tbl()} for flattening
- \texttt{dm\_filter()} for filtering
- \texttt{dm\_select\_tbl()} for creating a dm with only a subset of the tables
- \texttt{dm\_nycflights13()} for creating an example dm object
- \texttt{decompose\_table()} for table surgery
- \texttt{check\_key()} and \texttt{check\_subset()} for checking for key properties
- \texttt{examine\_cardinality()} for checking the cardinality of the relation between two tables

Examples

dm(trees, mtcars)
new_dm(list(trees = trees, mtcars = mtcars))
as_dm(list(trees = trees, mtcars = mtcars))

dm\_nycflights13()$airports
dm_nycflights13() %>% names()

copy_dm_to(
  dbplyr::src_memdb(),
  dm_nycflights13()
) %>%
  dm_get_con()

dm_nycflights13() %>% dm_get_tables()

dm_nycflights13() %>% dm_get_filters()

dm_nycflights13() %>% validate_dm()

is_dm(dm_nycflights13())

dm_nycflights13()["airports"]

dm_nycflights13()[["airports"]]

dm_nycflights13()$airports

---

**dm_add_fk**  
*Add foreign keys*

**Description**

dm_add_fk() marks the specified columns as the foreign key of table table with respect to a key of table ref_table. Usually the referenced columns are a primary key in ref_table, it is also possible to specify other columns via the ref_columns argument. If check == TRUE, then it will first check if the values in columns are a subset of the values of the key in table ref_table.

**Usage**

dm_add_fk(
  dm,
  table,
  columns,
  ref_table,
  ref_columns = NULL,
  ...,
  check = FALSE,
  on_delete = c("no_action", "cascade")
)

**Arguments**

- **dm**  
  A dm object.

- **table**  
  A table in the dm.

- **columns**  
  The columns of table which are to become the foreign key columns that reference ref_table. To define a compound key, use c(col1, col2).

- **ref_table**  
  The table which table will be referencing.
**ref_columns**

The column(s) of table which are to become the referenced column(s) in ref_table. By default, the primary key is used. To define a compound key, use c(col1, col2).

... These dots are for future extensions and must be empty.

**check**

Boolean, if TRUE, a check will be performed to determine if the values of columns are a subset of the values of the key column(s) of ref_table.

**on_delete**

[Experimental]

Defines behavior if a row in the parent table is deleted. - "no_action", the default, means that no action is taken and the operation is aborted if child rows exist - "cascade" means that the child row is also deleted This setting is picked up by copy_dm_to() with set_key_constraints = TRUE, and might be considered by dm_rows_delete() in a future version.

**Value**

An updated dm with an additional foreign key relation.

**See Also**

Other foreign key functions: dm_enum_fk_candidates(), dm_get_all_fks(), dm_rm_fk()

**Examples**

```r
nycflights_dm <- dm(
  planes = nycflights13::planes,
  flights = nycflights13::flights,
  weather = nycflights13::weather
)

nycflights_dm %>%
  dm_draw()

# Create foreign keys:
try(
  nycflights_dm %>%
    dm_add_pk(planes, tailnum) %>%
    dm_add_fk(flights, tailnum, planes) %>%
    dm_add_pk(weather, c(origin, time_hour)) %>%
    dm_add_fk(flights, c(origin, time_hour), weather) %>%
    dm_draw()
)
```
**dm_add_pk**

---

### Description

`dm_add_pk()` marks the specified columns as the primary key of the specified table. If `check == TRUE`, then it will first check if the given combination of columns is a unique key of the table. If `force == TRUE`, the function will replace an already set key, without altering foreign keys previously pointing to that primary key.

### Usage

```r
dm_add_pk(dm, table, columns, ..., check = FALSE, force = FALSE)
```

### Arguments

- **dm**: A `dm` object.
- **table**: A table in the `dm`.
- **columns**: Table columns, unquoted. To define a compound key, use `c(col1, col2)`.
- **...**: These dots are for future extensions and must be empty.
- **check**: Boolean, if `TRUE`, a check is made if the combination of columns is a unique key of the table.
- **force**: Boolean, if `FALSE` (default), an error will be thrown if there is already a primary key set for this table. If `TRUE`, a potential old pk is deleted before setting a new one.

### Value

An updated `dm` with an additional primary key.

### See Also

Other primary key functions: `dm_get_all_pks()`, `dm_has_pk()`, `dm_rm_pk()`, `enum_pk_candidates()`

### Examples

```r
nycflights_dm <- dm(
  planes = nycflights13::planes,
  airports = nycflights13::airports,
  weather = nycflights13::weather
)

nycflights_dm %>%
  dm_draw()

# Create primary keys:
```
nycflights_dm %>%
  dm_add_pk(planes, tailnum) %>%
  dm_add_pk(airports, faa, check = TRUE) %>%
  dm_add_pk(weather, c(origin, time_hour)) %>%
  dm_draw()

# Keys can be checked during creation:
try(
  nycflights_dm %>%
  dm_add_pk(planes, manufacturer, check = TRUE)
)

---

**dm_add_tbl**

Add tables to a dm

**Description**

Adds one or more new tables to a dm. Existing tables are not overwritten.

**Usage**

```
dm_add_tbl(dm, ..., repair = "unique", quiet = FALSE)
```

**Arguments**

- `dm` A dm object.
- `...` One or more tables to add to the dm. If no explicit name is given, the name of the expression is used.
- `repair` Either a string or a function. If a string, it must be one of "check_unique", "minimal", "unique", or "universal". If a function, it is invoked with a vector of minimal names and must return minimal names, otherwise an error is thrown.
  - Minimal names are never NULL or NA. When an element doesn’t have a name, its minimal name is an empty string.
  - Unique names are unique. A suffix is appended to duplicate names to make them unique.
  - Universal names are unique and syntactic, meaning that you can safely use the names as variables without causing a syntax error.
    
  The "check_unique" option doesn’t perform any name repair. Instead, an error is raised if the names don’t suit the "unique" criteria.
- `quiet` By default, the user is informed of any renaming caused by repairing the names. This only concerns unique and universal repairing. Set quiet to TRUE to silence the messages.

**Value**

The initial dm with the additional table(s).
**Description**

Create a single `dm` from two or more `dm` objects.

**Usage**

`dm_bind(..., repair = "check_unique", quiet = FALSE)`

**Arguments**

- `...`: `dm` objects to bind together.
- `repair`: Either a string or a function. If a string, it must be one of "check_unique", "minimal", "unique", or "universal". If a function, it is invoked with a vector of minimal names and must return minimal names, otherwise an error is thrown.
  - Minimal names are never NULL or NA. When an element doesn’t have a name, its minimal name is an empty string.
  - Unique names are unique. A suffix is appended to duplicate names to make them unique.
  - Universal names are unique and syntactic, meaning that you can safely use the names as variables without causing a syntax error.
  The "check_unique" option doesn’t perform any name repair. Instead, an error is raised if the names don’t suit the "unique" criteria.
- `quiet`: By default, the user is informed of any renaming caused by repairing the names. This only concerns unique and universal repairing. Set `quiet` to `TRUE` to silence the messages.

**Details**

The `dm` objects have to share the same `src`. By default table names need to be unique.
dm_disambiguate_cols

Value

dm containing the tables and key relations of all dm objects.

Examples

dm_1 <- dm_nycflights13()
dm_2 <- dm(mtcars, iris)
dm_bind(dm_1, dm_2)

dm_disambiguate_cols(dm, sep = ".", quiet = FALSE)

Arguments

dm A dm object.
sep The character variable that separates the names of the table and the names of the ambiguous columns.
quite Boolean. By default, this function lists the renamed columns in a message, pass TRUE to suppress this message.

Details

The function first checks if there are any column names that are not unique. If there are, those columns will be assigned new, unique, names by prefixing their existing name with the name of their table and a separator. Columns that act as primary or foreign keys will not be renamed because only the foreign key column will remain when two tables are joined, making that column name "unique" as well.

Value

A dm whose column names are unambiguous.

Examples

dm_nycflights13() %>%
dm_disambiguate_cols()
Draw a diagram of the data model

Description

\texttt{dm\_draw()} uses \texttt{DiagrammeR} to draw diagrams. Use \texttt{DiagrammeR\_rsvg::export\_svg()} to convert the diagram to an SVG file.

Usage

\begin{verbatim}
dm\_draw(
    dm,
    rankdir = "LR",
    col\_attr = NULL,
    view\_type = c("keys\_only", "all", "title\_only"),
    column\_Arrows = TRUE,
    graph\_attrs = "",
    node\_attrs = "",
    edge\_attrs = "",
    focus = NULL,
    graph\_name = "Data Model",
    ...
    column\_types = NULL
)
\end{verbatim}

Arguments

- \texttt{dm} A \texttt{dm} object.
- \texttt{rankdir} Graph attribute for direction (e.g., 'BT' = bottom \rightarrow top).
- \texttt{col\_attr} Deprecated, use \texttt{column\_types} instead.
- \texttt{view\_type} Can be "keys\_only" (default), "all" or "title\_only". It defines the level of details for rendering tables (only primary and foreign keys, all columns, or no columns).
- \texttt{column\_Arrows} Edges from columns to columns (default: TRUE).
- \texttt{graph\_attrs} Additional graph attributes.
- \texttt{node\_attrs} Additional node attributes.
- \texttt{edge\_attrs} Additional edge attributes.
- \texttt{focus} A list of parameters for rendering (table filter).
- \texttt{graph\_name} The name of the graph.
- \texttt{...} These dots are for future extensions and must be empty.
- \texttt{column\_types} Set to TRUE to show column types.

Value

An object of class \texttt{grViz} (see also \texttt{DiagrammeR::grViz()}), which, when printed, produces the output seen in the viewer as a side effect.
### dm_enum_fk_candidates

**Foreign key candidates**

**Description**

[Questioning]

Determine which columns would be good candidates to be used as foreign keys of a table, to reference the primary key column of another table of the `dm` object.

**Usage**

```r
dm_enum_fk_candidates(dm, table, ref_table, ...)
enum_fk_candidates(zoomed_dm, ref_table, ...)
```

**Arguments**

- **dm** A `dm` object.
- **table** The table whose columns should be tested for suitability as foreign keys.
- **ref_table** A table with a primary key.
- **...** These dots are for future extensions and must be empty.
- **zoomed_dm** A `dm` with a zoomed table.
Details

dm_enum_fk_candidates() first checks if ref_table has a primary key set, if not, an error is thrown.

If ref_table does have a primary key, then a join operation will be tried using that key as the by argument of join() to match it to each column of table. Attempting to join incompatible columns triggers an error.

The outcome of the join operation determines the value of the why column in the result:

• an empty value for a column of table that is a suitable foreign key candidate
• the count and percentage of missing matches for a column that is not suitable
• the error message triggered for unsuitable candidates that may include the types of mismatched columns

dm_enum_fk_candidates() works like dm_enum_fk_candidates() with the zoomed table as table.

Value

A tibble with the following columns:

- columns columns of table,
- candidate boolean: are these columns a candidate for a foreign key,
- why if not a candidate for a foreign key, explanation for this.

Life cycle

These functions are marked "questioning" because we are not yet sure about the interface, in particular if we need both dm_enum...() and enum...() variants. Changing the interface later seems harmless because these functions are most likely used interactively.

See Also

Other foreign key functions: dm_add_fk(), dm_get_all_fks(), dm_rm_fk()

Examples

```r
dm_nycflights13() %>%
  dm_enum_fk_candidates(flights, airports)
```

```r
dm_nycflights13() %>%
  dm_zoom_to(flights) %>%
  enum_fk_candidates(airports)
```
dm_examine_constraints

*Validate your data model*

**Description**

This function returns a tibble with information about which key constraints are met (`is_key = TRUE`) or violated (`FALSE`). The printing for this object is special, use `as_tibble()` to print as a regular tibble.

**Usage**

```r
dm_examine_constraints(dm, progress = NA)
```

**Arguments**

- **dm**
  - A `dm` object.
- **progress**
  - Whether to display a progress bar, if `NA` (the default) hide in non-interactive mode, show in interactive mode. Requires the 'progress' package.

**Details**

For the primary key constraints, it is tested if the values in the respective columns are all unique. For the foreign key constraints, the tests check if for each foreign key constraint, the values of the foreign key column form a subset of the values of the referenced column.

**Value**

A tibble with the following columns:

- **table** the table in the `dm`,
- **kind** "PK" or "FK",
- **columns** the table columns that define the key,
- **ref_table** for foreign keys, the referenced table,
- **is_key** logical,
- **problem** if `is_key = FALSE`, the reason for that.

**Examples**

```r
dm_nycflights13() %>%
dm_examine_constraints()
```
**dm_filter**

Filtering

**Description**

[Questioning]

Filtering a table of a dm object may affect other tables that are connected to it directly or indirectly via foreign key relations.

`dm_filter()` can be used to define filter conditions for tables using syntax that is similar to `dplyr::filter()`. These conditions will be stored in the `dm`, and executed immediately for the tables that they are referring to.

With `dm_apply_filters()`, all tables will be updated according to the filter conditions and the foreign key relations.

`dm_apply_filters_to_tbl()` retrieves one specific table of the dm that is updated according to the filter conditions and the foreign key relations.

**Usage**

```r
dm_filter(dm, table, ...)

dm_apply_filters(dm)

dm_apply_filters_to_tbl(dm, table)
```

**Arguments**

- **dm**: A dm object.
- **table**: A table in the dm.
- **...**: Logical predicates defined in terms of the variables in .data, passed on to `dplyr::filter()`. Multiple conditions are combined with & or |. Only the rows where the condition evaluates to TRUE are kept.

The arguments in ... are automatically quoted and evaluated in the context of the data frame. They support unquoting and splicing. See vignette("programming",package = "dplyr") for an introduction to these concepts.

**Details**

The effect of the stored filter conditions on the tables related to the filtered ones is only evaluated in one of the following scenarios:

1. Calling `dm_apply_filters()` or `compute()` (method for dm objects) on a dm: each filtered table potentially reduces the rows of all other tables connected to it by foreign key relations (cascading effect), leaving only the rows with corresponding key values. Tables that are not connected to any table with an active filter are left unchanged. This results in a new dm class object without any filter conditions.
2. Calling `dm_apply_filters_to_tbl()`: the remaining rows of the requested table are calculated by performing a sequence of semi-joins (`dplyr::semi_join()`) starting from each table that has been filtered to the requested table (similar to 1. but only for one table).

Several functions of the `dm` package will throw an error if filter conditions exist when they are called.

**Value**

For `dm_filter()`: an updated `dm` object (filter executed for given table, and condition stored).

For `dm_apply_filters()`: an updated `dm` object (filter effects evaluated for all tables).

For `dm_apply_filters_to_tbl()`, a table.

**Life cycle**

These functions are marked "questioning" because it feels wrong to tightly couple filtering with the data model. On the one hand, an overview of active filters is useful when specifying the base data set for an analysis in terms of column selections and row filters. However, these filter condition should be only of informative nature and never affect the results of other operations. We are working on formalizing the semantics of the underlying operations in order to present them in a cleaner interface.

Use `dm_zoom_to()` and `dplyr::filter()` to filter rows without registering the filter.

**Examples**

```r
dm_nyc <- dm_nycflights13()
dm_nyc_filtered <-
  dm_nycflights13() %>%
  dm_filter(airports, name == "John F Kennedy Intl")

dm_apply_filters_to_tbl(dm_nyc_filtered, flights)
dm_nyc_filtered %>%
  dm_apply_filters()

# If you want to keep only those rows in the parent tables
# whose primary key values appear as foreign key values in
# `flights`, you can set a `TRUE` filter in `flights`:
dm_nyc %>%
  dm_filter(flights, 1 == 1) %>%
  dm_apply_filters() %>%
  dm_nrow()

# note that in this example, the only affected table is
# `airports` because the departure airports in `flights` are
# only the three New York airports.

dm_nyc %>%
  dm_filter(planes, engine %in% c("Reciprocating", "4 Cycle")) %>%
```

```
**dm_financial**

create()

---

**dm_financial**  
*Creates a dm object for the Financial data*

**Description**

*[Experimental]*

`dm_financial()` creates an example `dm` object from the tables at https://relational.fit.cvut.cz/dataset/Financial. The connection is established once per session, subsequent calls return the same connection.

`dm_financial_sqlite()` copies the data to a temporary SQLite database. The data is downloaded once per session, subsequent calls return the same database. The `trans` table is excluded due to its size.

**Usage**

```r
dm_financial()

dm_financial_sqlite()
```

**Value**

A `dm` object.

**Examples**

```r
dm_financial() %>%
  dm_draw()
```

---

**dm_flatten_to_tbl**  
*Flatten a part of a dm into a wide table*

**Description**

`dm_flatten_to_tbl()` and `dm_squash_to_tbl()` gather all information of interest in one place in a wide table. Both functions perform a disambiguation of column names and a cascade of joins.

**Usage**

```r
dm_flatten_to_tbl(dm, start, ..., join = left_join)

dm_squash_to_tbl(dm, start, ..., join = left_join)
```
Arguments

- **dm**: A `dm` object.

- **start**: The table from which all outgoing foreign key relations are considered when establishing a processing order for the joins. An interesting choice could be for example a fact table in a star schema.

- **...**: Unquoted names of the tables to be included in addition to the `start` table. The order of the tables here determines the order of the joins. If the argument is empty, all tables that can be reached will be included. If this includes tables that are not direct neighbors of `start`, it will only work with `dm_squash_to_tbl()` (given one of the allowed join-methods). `tidyselect` is supported, see `dplyr::select()` for details on the semantics.

- **join**: The type of join to be performed, see `dplyr::join()`.

Details

With `...` left empty, this function will join together all the tables of your `dm` object that can be reached from the `start` table, in the direction of the foreign key relations (pointing from the child tables to the parent tables), using the foreign key relations to determine the argument by for the necessary joins. The result is one table with unique column names. Use the `...` argument if you would like to control which tables should be joined to the `start` table.

How does filtering affect the result?

**Case 1**, either no filter conditions are set in the `dm`, or set only in the part that is unconnected to the `start` table: The necessary disambiguations of the column names are performed first. Then all involved foreign tables are joined to the `start` table successively, with the join function given in the `join` argument.

**Case 2**, filter conditions are set for at least one table that is connected to `start`: First, disambiguation will be performed if necessary. The `start` table is then calculated using `tbl(dm,"start")`. This implies that the effect of the filters on this table is taken into account. For `right_join`, `full_join` and `nest_join`, an error is thrown if any filters are set because filters will not affect the right hand side tables and the result will therefore be incorrect in general (calculating the effects on all RHS-tables would also be time-consuming, and is not supported; if desired, call `dm_apply_filters()` first to achieve that effect). For all other join types, filtering only the `start` table is enough because the effect is passed on by successive joins.

Mind that calling `dm_flatten_to_tbl()` with `join = right_join` and no table order determined in the `...` argument will not lead to a well-defined result if two or more foreign tables are to be joined to `start`. The resulting table would depend on the order the tables that are listed in the `dm`. Therefore, trying this will result in a warning.

Since `join = nest_join()` does not make sense in this direction (LHS = child table, RHS = parent table: for valid key constraints each nested column entry would be a tibble of one row), an error will be thrown if this method is chosen.

Value

A single table that results from consecutively joining all affected tables to the `start` table.
See Also

Other flattening functions: `dm_join_to_tbl()`

Examples

```r
dm_nycflights13() %>%
dm_select_tbl(-weather) %>%
dm_flatten_to_tbl(flights)
```

---

**dm_from_src**

Load a dm from a remote data source

Description

`dm_from_src()` creates a `dm` from some or all tables in a `src` (a database or an environment) or which are accessible via a `DBI::DBIConnection`. For Postgres and SQL Server databases, primary and foreign keys are imported from the database.

Usage

```r
dm_from_src(src = NULL, table_names = NULL, learn_keys = NULL, ...)
```

Arguments

src

A dplyr table source object or a `DBI::DBIConnection` object is accepted.

table_names

A character vector of the names of the tables to include.

learn_keys

[Experimental] Set to `TRUE` to query the definition of primary and foreign keys from the database. Currently works only for Postgres and SQL Server databases. The default attempts to query and issues an informative message.

... [Experimental]

Additional parameters for the schema learning query.

- schema: supported for MSSQL (default: "dbo"), Postgres (default: "public"), and MariaDB/MySQL (default: current database). Learn the tables in a specific schema (or database for MariaDB/MySQL).
- dbname: supported for MSSQL. Access different databases on the connected MSSQL-server; default: active database.
- table_type: supported for Postgres (default: "BASE TABLE"). Specify the table type. Options are:
  1. "BASE TABLE" for a persistent table (normal table type)
  2. "VIEW" for a view
  3. "FOREIGN TABLE" for a foreign table
  4. "LOCAL TEMPORARY" for a temporary table
Value
A `dm` object.

Examples

```r
con <- DBI::dbConnect(
  RMariaDB::MariaDB(),
  username = "guest",
  password = "relational",
  dbname = "Financial_ijs",
  host = "relational.fit.cvut.cz"
)

dm_from_src(con)

DBI::dbDisconnect(con)
```

---

**dm_get_all_fks**  
*Get foreign key constraints*

Description
Get a summary of all foreign key relations in a `dm`.

Usage
```
dm_get_all_fks(dm, parent_table = NULL, ...)
```

Arguments
- **dm**
  A `dm` object.
- **parent_table**  
  One or more table names, as character vector, to return foreign key information for. The default `NULL` returns information for all tables.
- **...**
  These dots are for future extensions and must be empty.

Value
A tibble with the following columns:
- **child_table**  
  child table,
- **child_fk_cols**  
  foreign key column(s) in child table as list of character vectors,
- **parent_table**  
  parent table,
- **parent_key_cols**  
  key column(s) in parent table as list of character vectors.
- **on_delete**  
  behavior on deletion of rows in the parent table.
dm_get_all_pks

See Also
Other foreign key functions: dm_add_fk(), dm_enum_fk_candidates(), dm_rm_fk()

Examples

dm_nycflights13() %>%
  dm_get_all_fks()

---

dm_get_all_pks Get all primary keys of a dm object

Description
dm_get_all_pks() checks the dm object for set primary keys and returns the tables, the respective primary key columns and their classes.

Usage
dm_get_all_pks(dm, table = NULL, ...)

Arguments
- **dm**: A dm object.
- **table**: One or more table names, as character vector, to return primary key information for. The default NULL returns information for all tables.
- **...**: These dots are for future extensions and must be empty.

Value
A tibble with the following columns:
- **table**: table name,
- **pk_cols**: column name(s) of primary key, as list of character vectors.

See Also
Other primary key functions: dm_add_pk(), dm_has_pk(), dm_rm_pk(), enum_pk_candidates()

Examples

dm_nycflights13() %>%
  dm_get_all_pks()
**dm_get_filters**  
*Get filter expressions*

**Description**

`dm_get_filters()` returns the filter expressions that have been applied to a `dm` object. These filter expressions are not intended for evaluation, only for information.

**Usage**

```
dm_get_filters(x)
```

**Arguments**

- `x`  
  An object.

**Value**

A tibble with the following columns:

- `table`  
  Table that was filtered,

- `filter`  
  The filter expression,

- `zoomed`  
  Logical, does the filter condition relate to the zoomed table.

---

**dm_get_referencing_tables**  
*Get the names of referencing tables*

**Description**

This function returns the names of all tables that point to the primary key of a table.

**Usage**

```
dm_get_referencing_tables(dm, table)
```

**Arguments**

- `dm`  
  A `dm` object.

- `table`  
  A table in the `dm`.

**Value**

A character vector of the names of the tables that point to the primary key of `table`. 
See Also

Other functions utilizing foreign key relations: `dm_is_referenced()`

Examples

```r
# Check for primary key

# Check if the given table has columns marked as its primary key.

# Examples

dm_nycflights13() %>%
  dm_get_referencing_tables(airports)

dm_nycflights13() %>%
  dm_get_referencing_tables(flights)
```

---

**Description**

dm_has_pk() checks if a given table has columns marked as its primary key.

**Usage**

```r
dm_has_pk(dm, table, ...)
```

**Arguments**

- `dm` A dm object.
- `table` A table in the dm.
- `...` These dots are for future extensions and must be empty.

**Value**

A logical value: TRUE if the given table has a primary key, FALSE otherwise.

**See Also**

Other primary key functions: `dm_add_pk()`, `dm_get_all_pks()`, `dm_rm_pk()`, `enum_pk_candidates()`

**Examples**

```r
# Examples

dm_nycflights13() %>%
  dm_has_pk(flights)

dm_nycflights13() %>%
  dm_has_pk(planes)
```
**dm_is_referenced**  
*Check foreign key reference*

**Description**

Is a table of a dm referenced by another table?

**Usage**

\[
\text{dm_is_referenced}(\text{dm}, \text{table})
\]

**Arguments**

- **dm**  
  A dm object.

- **table**  
  A table in the dm.

**Value**

TRUE if at least one foreign key exists that points to the primary key of the table argument, FALSE otherwise.

**See Also**

Other functions utilizing foreign key relations: \textit{dm_get_referencing_tables()}

**Examples**

\[
\text{dm_nycflights13()} \%>\%
   \text{dm_is_referenced(airports)}
\text{dm_nycflights13()} \%>\%
   \text{dm_is_referenced(flights)}
\]

---

**dm_join_to_tbl**  
*Join two tables*

**Description**

A join of a desired type is performed between table_1 and table_2. The two tables need to be directly connected by a foreign key relation. Since this function is a wrapper around \textit{dm_flatten_to_tbl()}, the LHS of the join will always be a "child table", i.e. a table referencing the other table.

**Usage**

\[
\text{dm_join_to_tbl}(\text{dm}, \text{table}_1, \text{table}_2, \text{join} = \text{left_join})
\]
dm_mutate_tbl

Arguments

- **dm**: A `dm` object.
- **table_1**: One of the tables involved in the join.
- **table_2**: The second table of the join.
- **join**: The type of join to be performed, see `dplyr::join()`.

Value

The resulting table of the join.

See Also

Other flattening functions: `dm_flatten_to_tbl()`

Examples

```r

dm_nycflights13() %>%
  dm_join_to_tbl(airports, flights)

# same result is achieved with:

dm_nycflights13() %>%
  dm_join_to_tbl(flights, airports)

# this gives an error, because the tables are not directly linked to each other:
try(
  dm_nycflights13() %>%
  dm_join_to_tbl(airlines, airports)
)
```

---

**dm_mutate_tbl**

*Update tables in a dm*

Description

[Experimental]

Updates one or more existing tables in a `dm`. For now, the column names must be identical. This restriction may be levied optionally in the future.

Usage

```r

dm_mutate_tbl(dm, ...)
```

Arguments

- **dm**: A `dm` object.
- **...**: One or more tables to update in the `dm`. Must be named.
See Also

`dm_add_tbl()`, `dm_rm_tbl()`

Examples

```r
dm_nycflights13() %>%
  dm_mutate_tbl(flights = nycflights13::flights[1:3, ])
```

<table>
<thead>
<tr>
<th><code>dm_nrow</code></th>
<th>Number of rows</th>
</tr>
</thead>
</table>

Description

Returns a named vector with the number of rows for each table.

Usage

```r
dm_nrow(dm)
```

Arguments

- `dm` A `dm` object.

Value

A named vector with the number of rows for each table.

Examples

```r
dm_nycflights13() %>%
  dm_filter(airports, faa %in% c("EWR", "LGA")) %>%
  dm_apply_filters() %>%
  dm_nrow()
```
**dm_nycflights13**

Creates a dm object for the nycflights13 data

---

**Description**

Creates an example dm object from the tables in nycflights13, along with the references. See nycflights13::flights for a description of the data. As described in nycflights13::planes, the relationship between the flights table and the planes tables is "weak", it does not satisfy data integrity constraints.

**Usage**

```r
dm_nycflights13(cycle = FALSE, color = TRUE, subset = TRUE, compound = TRUE)
```

**Arguments**

- **cycle**
  - Boolean. If FALSE (default), only one foreign key relation (from flights$origin to airports$faa) between the flights table and the airports table is established. If TRUE, a dm object with a double reference between those tables will be produced.

- **color**
  - Boolean, if TRUE (default), the resulting dm object will have colors assigned to different tables for visualization with dm_draw().

- **subset**
  - Boolean, if TRUE (default), the flights table is reduced to flights with column day equal to 10.

- **compound**
  - Boolean, if FALSE, no link will be established between tables flights and weather, because this requires compound keys.

**Value**

A dm object consisting of nycflights13 tables, complete with primary and foreign keys and optionally colored.

**Examples**

```r
dm_nycflights13() %>%
dm_draw()
```
Description

`dm_paste()` takes an existing `dm` and emits the code necessary for its creation.

Usage

```r
dm_paste(dm, select = NULL, ..., tab_width = 2, options = NULL, path = NULL)
```

Arguments

- **dm**: A `dm` object.
- **select**: Deprecated, see "select" in the options argument.
- **...**: Must be empty.
- **tab_width**: Indentation width for code from the second line onwards
- **options**: Formatting options. A character vector containing some of:
  - "tables": `tibble()` calls for empty table definitions derived from `dm_ptype()`, overrides "select".
  - "select": `dm_select()` statements for columns that are part of the `dm`.
  - "keys": `dm_add_pk()` and `dm_add_fk()` statements for adding keys.
  - "color": `dm_set_colors()` statements to set color.
  - "all": All options above except "select"
- **path**: Output file, if `NULL` the code is printed to the console.

Details

The code emitted by the function reproduces the structure of the `dm` object. The options argument controls the level of detail: keys, colors, table definitions. Data in the tables is never included, see `dm_ptype()` for the underlying logic.

Value

Code for producing the prototype of the given `dm`.

Examples

```r
dm() %>%
  dm_paste()

dm_nycflights13() %>%
  dm_paste()
```
**dm_ptype**

Prototype for a dm object

**Description**

[Experimental]

The prototype contains all tables, all primary and foreign keys, but no data. All tables are truncated and converted to zero-row tibbles. Column names retain their type. This is useful for performing creation and population of a database in separate steps.

**Usage**

```r
dm_ptype(dm)
```

**Arguments**

- **dm**: A dm object.

**Examples**

```r
dm_nycflights13() %>%
dm_paste(options = "select")
```

```
---

**dm_rename**

Rename columns

**Description**

Rename the columns of your dm using syntax that is similar to dplyr::rename().

**Usage**

```r
dm_rename(dm, table, ...)
```
Arguments

- **dm**: A `dm` object.
- **table**: A table in the `dm`.
- **...**: One or more unquoted expressions separated by commas. You can treat variable names as if they were positions, and use expressions like x:y to select the ranges of variables.
- **Use named arguments, e.g. new_name = old_name, to rename the selected variables.**
- **The arguments in ... are automatically quoted and evaluated in a context where column names represent column positions. They also support unquoting and splicing. See vignette("programming",package = "dplyr") for an introduction to those concepts.**
- **See select helpers for more details, and the examples about tidyselect helpers, such as starts_with(), everything(), ...**

Details

If key columns are renamed, then the meta-information of the `dm` is updated accordingly.

Value

An updated `dm` with the columns of `table` renamed.

Examples

```r
dm_nycflights13() %>%
  dm_rename(airports, code = faa, altitude = alt)
```

### Description

`dm_rm_fk()` can remove either one reference between two tables, or multiple references at once (with a message). An error is thrown if no matching foreign key is found.

Usage

```r
dm_rm_fk(
  dm,
  table = NULL,
  columns = NULL,
  ref_table = NULL,
  ref_columns = NULL,
  ...
)
```
### Arguments

- **dm**: A `dm` object.
- **table**: A table in the `dm`. Pass `NULL` to remove all matching keys.
- **columns**: Table columns, unquoted. To refer to a compound key, use `c(col1,col2)`. Pass `NULL` (the default) to remove all matching keys.
- **ref_table**: The table referenced by the `table` argument. Pass `NULL` to remove all matching keys.
- **ref_columns**: The columns of `table` that should no longer be referencing the primary key of `ref_table`. To refer to a compound key, use `c(col1,col2)`.
- **...**: These dots are for future extensions and must be empty.

### Value

An updated `dm` without the matching foreign key relation(s).

### See Also

Other foreign key functions: `dm_add_fk()`, `dm_enum_fk_candidates()`, `dm_get_all_fks()`

### Examples

```r
dm_nycflights13(cycle = TRUE) %>%
  dm_rm_fk(flights, dest, airports) %>%
  dm_draw()
```

---

### dm_rm_pk

Remove a primary key

---

### Description

`dm_rm_pk()` removes one or more primary keys from a table and leaves the `dm` object otherwise unaltered. An error is thrown if no private key matches the selection criteria. If the selection criteria are ambiguous, a message with unambiguous replacement code is shown. Foreign keys are never removed.

### Usage

```r
dm_rm_pk(dm, table = NULL, columns = NULL, ..., fail_fk = TRUE)
```
Arguments

- **dm**: A `dm` object.
- **table**: A table in the `dm`. Pass `NULL` to remove all matching keys.
- **columns**: Table columns, unquoted. To refer to a compound key, use `c(col1, col2)`. Pass `NULL` (the default) to remove all matching keys.
- **...**: These dots are for future extensions and must be empty.
- **fail_fk**: Boolean: if `TRUE` (default), will throw an error if there are foreign keys addressing the primary key that is to be removed.

Value

An updated `dm` without the indicated primary key(s).

See Also

Other primary key functions: `dm_add_pk()`, `dm_get_all_pks()`, `dm_has_pk()`, `enum_pk_candidates()`

Examples

```r
  dm_nycflights13() %>%
  dm_rm_pk(airports, fail_fk = FALSE) %>%
  dm_draw()
```

---

**dm_rm_tbl**

*Remove tables*

Description

Removes one or more tables from a `dm`.

Usage

```r
  dm_rm_tbl(dm, ...)
```

Arguments

- **dm**: A `dm` object.
- **...**: One or more unquoted table names to remove from the `dm`. `tidyselect` is supported, see `dplyr::select()` for details on the semantics.

Value

The `dm` without the removed table(s) that were present in the initial `dm`. 
See Also

dm_add_tbl(), dm_select_tbl()

Examples

dm_nycflights13() %>%
  dm_rm_tbl(airports)

Argument

dm A dm object.
table A table in the dm.
... One or more unquoted expressions separated by commas. You can treat variable names as if they were positions, and use expressions like x:y to select the ranges of variables.

Use named arguments, e.g. new_name = old_name, to rename the selected variables.
The arguments in ... are automatically quoted and evaluated in a context where column names represent column positions. They also support unquoting and splicing. See vignette("programming", package = "dplyr") for an introduction to those concepts.

See select helpers for more details, and the examples about tidyselect helpers, such as starts_with(), everything(), ...

Details

If key columns are renamed, then the meta-information of the dm is updated accordingly. If key columns are removed, then all related relations are dropped as well.

Value

An updated dm with the columns of table reduced and/or renamed.
Examples

```r
dm_nycflights13() %>%
  dm_select(airports, code = faa, altitude = alt)
```

---

**dm_select_tbl**  *Select and rename tables*

**Description**

dm_select_tbl() keeps the selected tables and their relationships, optionally renaming them.  
dm_rename_tbl() renames tables.

**Usage**

```r
dm_select_tbl(dm, ...)
dm_rename_tbl(dm, ...)
```

**Arguments**

- `dm`  
  A `dm` object.
- `...`  
  One or more table names of the tables of the `dm` object. tidyselect is supported, see `dplyr::select()` for details on the semantics.

**Value**

The input `dm` with tables renamed or removed.

**See Also**

- `dm_rm_tbl()`

**Examples**

```r
dm_nycflights13() %>%
  dm_select_tbl(airports, fl = flights)
```

```r
dm_nycflights13() %>%
  dm_rename_tbl(ap = airports, fl = flights)
```
**dm_set_colors**

**Description**

`dm_set_colors()` allows to define the colors that will be used to display the tables of the data model with `dm_draw()`. The colors can either be either specified with hex color codes or using the names of the built-in R colors. An overview of the colors corresponding to the standard color names can be found at the bottom of [http://rpubs.com/krlmlr/colors](http://rpubs.com/krlmlr/colors).

`dm_get_colors()` returns the colors defined for a data model.

`dm_get_available_colors()` returns an overview of the names of the available colors. These are the standard colors also returned by `grDevices::colors()` plus a default table color with the name "default".

**Usage**

```r
dm_set_colors(dm, 
...)
dm_get_colors(dm)
dm_get_available_colors()
```

**Arguments**

- `dm` A `dm` object.
- `...` Colors to set in the form `color = table`. Allowed colors are all hex coded colors (quoted) and the color names from `dm_get_available_colors()`. `tidyselect` is supported, see `dplyr::select()` for details on the semantics.

**Value**

For `dm_set_colors()`: the updated data model.

For `dm_get_colors()`, a two-column tibble with one row per table.

For `dm_get_available_colors()`, a vector with the available colors.

**Examples**

```r
dm_nycflights13(color = FALSE) %>%
  dm_set_colors(
    darkblue = starts_with("air"),
    "#5986C4" = flights
  ) %>%
  dm_draw()

# Splicing is supported:
```
nyc_cols <-
  dm_nycflights13() %>%
  dm_get_colors()

nyc_cols

dm_nycflights13(color = FALSE) %>%
  dm_set_colors(!!!nyc_cols) %>%
  dm_draw()

dm_zoom_to

Mark table for manipulation

Description

Zooming to a table of a dm allows for the use of many dplyrverbs directly on this table, while retaining the context of the dm object.
dm_zoom_to() zooms to the given table.
dm_update_zoomed() overwrites the originally zoomed table with the manipulated table. The filter conditions for the zoomed table are added to the original filter conditions.
dm_insert_zoomed() adds a new table to the dm.
dm_discard_zoomed() discards the zoomed table and returns the dm as it was before zooming.
Please refer to vignette("tech-db-zoom",package = "dm") for a more detailed introduction.

Usage

dm_zoom_to(dm, table)
dm_insert_zoomed(dm, new_tbl_name = NULL, repair = "unique", quiet = FALSE)
dm_update_zoomed(dm)
dm_discard_zoomed(dm)

Arguments

dm A dm object.
table A table in the dm.
new_tbl_name Name of the new table.
repair Either a string or a function. If a string, it must be one of "check_unique", "minimal", "unique", or "universal". If a function, it is invoked with a vector of minimal names and must return minimal names, otherwise an error is thrown.
  • Minimal names are never NULL or NA. When an element doesn’t have a name, its minimal name is an empty string.
Unique names are unique. A suffix is appended to duplicate names to make them unique.

Universal names are unique and syntactic, meaning that you can safely use the names as variables without causing a syntax error.

The "check_unique" option doesn’t perform any name repair. Instead, an error is raised if the names don’t suit the "unique" criteria.

By default, the user is informed of any renaming caused by repairing the names. This only concerns unique and universal repairing. Set quiet to TRUE to silence the messages.

Whenever possible, the key relations of the original table are transferred to the resulting table when using `dm_insert_zoomed()` or `dm_update_zoomed()`.

Functions from `dplyr` that are supported for a zoomed_dm: `group_by()`, `summarise()`, `mutate()`, `transmute()`, `filter()`, `select()`, `rename()` and `ungroup()`. You can use these functions just like you would with a normal table.

Calling `filter()` on a zoomed dm is different from calling `dm_filter()`: only with the latter, the filter expression is added to the list of table filters stored in the dm.

Furthermore, different `join()`-variants from `dplyr` are also supported, e.g. `left_join()` and `semi_join()`. (Support for `nest_join()` is planned.) The join-methods for zoomed_dm infer the columns to join by from the primary and foreign keys, and have an extra argument select that allows choosing the columns of the RHS table.

And - last but not least - also the tidyr-functions `unite()` and `separate()` are supported for zoomed_dm.

For `dm_zoom_to()`: A zoomed_dm object.

For `dm_insert_zoomed()`, `dm_update_zoomed()` and `dm_discard_zoomed()`: A dm object.

```
flights_zoomed <- dm_zoom_to(dm_nycflights13(), flights)
flights_zoomed
flights_zoomed_transformed <-
  flights_zoomed %>%
  mutate(am_pm_dep = ifelse(dep_time < 1200, "am", "pm")) %>%
  # 'by'-argument of `left_join()` can be explicitly given
  # otherwise the key-relation is used
  left_join(airports) %>%
  select(year:dep_time, am_pm_dep, everything())
flights_zoomed_transformed
```
### dplyr_join

**dplyr join methods for zoomed dm objects**

**Description**

Use these methods without the `.zoomed_dm` suffix (see examples).

**Usage**

```r
## S3 method for class 'zoomed_dm'
left_join(x, y, by = NULL, copy = NULL, suffix = NULL, select = NULL, ...)

## S3 method for class 'zoomed_dm'
inner_join(x, y, by = NULL, copy = NULL, suffix = NULL, select = NULL, ...)

## S3 method for class 'zoomed_dm'
full_join(x, y, by = NULL, copy = NULL, suffix = NULL, select = NULL, ...)

## S3 method for class 'zoomed_dm'
right_join(x, y, by = NULL, copy = NULL, suffix = NULL, select = NULL, ...)

## S3 method for class 'zoomed_dm'
semi_join(x, y, by = NULL, copy = NULL, suffix = NULL, select = NULL, ...)

## S3 method for class 'zoomed_dm'
anti_join(x, y, by = NULL, copy = NULL, suffix = NULL, select = NULL, ...)
```

**Arguments**

- `x, y` 
  tbsls to join. `x` is the zoomed `dm` and `y` is another table in the `dm`.

- `by` 
  If left `NULL` (default), the join will be performed by via the foreign key relation that exists between the originally zoomed table (now `x`) and the other table (`y`). If you provide a value (for the syntax see `dplyr::join`), you can also join tables that are not connected in the `dm`. 
copy Disabled, since all tables in a dm are by definition on the same src.
suffix Disabled, since columns are disambiguated automatically if necessary, changing
the column names to table_name.column_name.
select Select a subset of the RHS-table's columns, the syntax being select = c(col_1, col_2, col_3)
(unquoted or quoted). This argument is specific for the join-methods for zoomed_dm.
The table's by column(s) are automatically added if missing in the selection.

Examples

```r
flights_dm <- dm_nycflights13()
flights_dm %>%
  left_join(airports, select = c(faa, name))

# this should illustrate that tables don't necessarily need to be connected
flights_dm %>%
  semi_join(airlines, by = "name")
```

Description

Use these methods without the '.zoomed_dm' suffix (see examples).

Usage

```r
## S3 method for class 'zoomed_dm'
filter(.data, ...)

## S3 method for class 'zoomed_dm'
mutate(.data, ...)

## S3 method for class 'zoomed_dm'
transmute(.data, ...)

## S3 method for class 'zoomed_dm'
select(.data, ...)

## S3 method for class 'zoomed_dm'
relocate(.data, ..., .before = NULL, .after = NULL)

## S3 method for class 'zoomed_dm'
rename(.data, ...)
```
## S3 method for class 'zoomed_dm'
distinct(.data, ..., .keep_all = FALSE)

## S3 method for class 'zoomed_dm'
arrange(.data, ...)

## S3 method for class 'zoomed_dm'
slice(.data, ..., .keep_pk = NULL)

## S3 method for class 'zoomed_dm'
group_by(.data, ...)

## S3 method for class 'zoomed_dm'
ungroup(x, ...)

## S3 method for class 'zoomed_dm'
summarise(.data, ...)

## S3 method for class 'zoomed_dm'
count(
  x,
  ..., 
  wt = NULL,
  sort = FALSE,
  name = NULL,
  .drop = group_by_drop_default(x)
)

## S3 method for class 'zoomed_dm'
tally(x, ...)

## S3 method for class 'zoomed_dm'
pull(.data, var = -1, ...)

## S3 method for class 'zoomed_dm'
compute(x, ...)

### Arguments

- **.data**
  - object of class zoomed_dm
- **...**
  - see corresponding function in package dplyr or tidyr
- **.before**
  - <tidy-select> Destination of columns selected by .... Supplying neither will move columns to the left-hand side; specifying both is an error.
- **.after**
  - <tidy-select> Destination of columns selected by .... Supplying neither will move columns to the left-hand side; specifying both is an error.
- **.keep_all**
  - For distinct.zoomed_dm(): see dplyr::distinct
enum_pk_candidates

.. _keep_pk:

**keep_pk**
For `slice.zoomed_dm`: Logical, if TRUE, the primary key will be retained during this transformation. If FALSE, it will be dropped. By default, the value is NULL, which causes the function to issue a message in case a primary key is available for the zoomed table. This argument is specific for the `slice.zoomed_dm()` method.

.. _x:

**x**
For `ungroup.zoomed_dm`: object of class `zoomed_dm`

.. _wt:

**wt**
<code data-masking> Frequency weights. Can be NULL or a variable:
  * If NULL (the default), counts the number of rows in each group.
  * If a variable, computes `sum(wt)` for each group.

.. _sort:

**sort**
If TRUE, will show the largest groups at the top.

.. _name:

**name**
The name of the new column in the output. If omitted, it will default to n. If there’s already a column called n, it will error, and require you to specify the name.

.. _drop:

**drop**
For `count()`: if FALSE will include counts for empty groups (i.e. for levels of factors that don’t exist in the data). Deprecated in `add_count()` since it didn’t actually affect the output.

.. _var:

**var**
A variable specified as:
  * a literal variable name
  * a positive integer, giving the position counting from the left
  * a negative integer, giving the position counting from the right.

The default returns the last column (on the assumption that’s the column you’ve created most recently).

This argument is taken by expression and supports quasiquotation (you can unquote column names and column locations).

**Examples**

```r
zoomed <- dm_nycflights13() %>%
  dm_zoom_to(flights) %>%
  group_by(month) %>%
  arrange(desc(day)) %>%
  summarize(avg_air_time = mean(air_time, na.rm = TRUE))
zoomed
```

```
  dm_insert_zoomed(zoomed, new_tbl_name = "avg_air_time_per_month")
```

**Description**

**[Questioning]**

`enum_pk_candidates()` checks for each column of a table if the column contains only unique values, and is thus a suitable candidate for a primary key of the table.

`dm_enum_pk_candidates()` performs these checks for a table in a `dm` object.
Usage

`enum_pk_candidates(table, ...)`

`dm_enum_pk_candidates(dm, table, ...)`

Arguments

`table` A table in the `dm`.

`...` These dots are for future extensions and must be empty.

`dm` A `dm` object.

Value

A tibble with the following columns:

- `columns` columns of `table`
- `candidate` boolean: are these columns a candidate for a primary key?
- `why` if not a candidate for a primary key column, explanation for this.

Life cycle

These functions are marked "questioning" because we are not yet sure about the interface, in particular if we need both `dm_enum...()` and `enum...()` variants. Changing the interface later seems harmless because these functions are most likely used interactively.

See Also

Other primary key functions: `dm_add_pk()`, `dm_get_all_pks()`, `dm_has_pk()`, `dm_rm_pk()`

Examples

```r
nycflights13::flights %>%
  enum_pk_candidates()
```

```r
dm_nycflights13() %>%
  dm_enum_pk_candidates(airports)
```
Description

All check_cardinality_*() functions test the following conditions:

1. Is pk_column a unique key for parent_table?
2. Is the set of values in fk_column of child_table a subset of the set of values of pk_column?
3. Does the relation between the two tables of the data model meet the cardinality requirements?

examine_cardinality() also checks the first two points and subsequently determines the type of cardinality.

Usage

check_cardinality_0_n(parent_table, pk_column, child_table, fk_column)
check_cardinality_1_n(parent_table, pk_column, child_table, fk_column)
check_cardinality_1_1(parent_table, pk_column, child_table, fk_column)
check_cardinality_0_1(parent_table, pk_column, child_table, fk_column)
examine_cardinality(parent_table, pk_column, child_table, fk_column)

Arguments

parent_table            Data frame.
pk_column               Columns of parent_table that have to be one of its unique keys, for multiple columns use c(col1,col2).
child_table             Data frame.
fk_column               Columns of child_table that have to be a foreign key candidate to pk_column in parent_table, for multiple columns use c(col1,col2).

Details

All cardinality-functions accept a parent_table (data frame), column names of this table, a child_table, and column names of the child table. The given columns of the parent_table have to be one of its unique keys (no duplicates are allowed). Furthermore, in all cases, the set of combinations of the child table’s columns have to be a subset of the combinations of values of the parent table’s columns.

The cardinality specifications "0_n", "1_n", "0_1", "1_1" refer to the expected relation that the child table has with the parent table. "0", "1" and "n" refer to the occurrences of value combinations in the columns of the child table that correspond to each combination in the columns of the parent table. "n" means "more than one" in this context, with no upper limit.
"0_n": each combination of pk_column values has at least 0 and at most n corresponding occurrences in the columns of the child table (which translates to no further restrictions).

"1_n": each combination of pk_column values has at least 1 and at most n corresponding occurrences in the columns of the child table. This means that there is a "surjective" mapping from the child table to the parent table w.r.t. the specified columns, i.e. each combination in the parent table columns exists at least once in the child table columns.

"0_1": each combination of pk_column values has at least 0 and at most 1 corresponding occurrence in the column of the child table. This means that there is a "injective" mapping from the child table to the parent table w.r.t. the specified columns, i.e. no combination of values in the parent table columns is addressed multiple times. But not all of the parent table column values have to be referred to.

"1_1": each combination of pk_column values occurs exactly once in the corresponding columns of the child table. This means that there is a "bijective" ("injective" AND "surjective") mapping between the child table and the parent table w.r.t. the specified columns, i.e. the respective sets of combinations within the two sets of columns are equal and there are no duplicates in either of them.

Finally, examine_cardinality() tests for and returns the nature of the relationship (injective, surjective, bijective, or none of these) between the two given sets of columns. If either pk_column is not a unique key of parent_table or the values of fk_column are not a subset of the values in pk_column, the requirements for a cardinality test is not fulfilled. No error will be thrown, but the result will contain the information which prerequisite was violated.

Value

For check_cardinality_*(): Functions return parent_table, invisibly, if the check is passed, to support pipes. Otherwise an error is thrown and the reason for it is explained.

For examine_cardinality(): Returns a character variable specifying the type of relationship between the two columns.

Examples

d1 <- tibble::tibble(a = 1:5)
d2 <- tibble::tibble(c = c(1:5, 5))
d3 <- tibble::tibble(c = 1:4)

# This does not pass, `c` is not unique key of d2:
try(check_cardinality_0_n(d2, c, d1, a))

# This passes, multiple values in d2$c are allowed:
check_cardinality_0_n(d1, a, d2, c)

# This does not pass, injectivity is violated:
try(check_cardinality_1_1(d1, a, d2, c))

# This passes:
check_cardinality_0_1(d1, a, d3, c)

# Returns the kind of cardinality
examine_cardinality(d1, a, d2, c)
get_returned_rows

Extract and check the RETURNING rows

Description

[Experimental]

get_returned_rows() extracts the RETURNING rows produced by rows_insert(), rows_update(), rows_upsert(), or rows_delete() if called with the returning argument. An error is raised if this information is not available.

has_returned_rows() checks if x has stored RETURNING rows produced by rows_insert(), rows_update(), rows_upsert(), or rows_delete().

Usage

get_returned_rows(x)

has_returned_rows(x)

Arguments

x       A lazy tbl.

Value

For get_returned_rows(), a tibble.
For has_returned_rows(), a scalar logical.

head.zoomed_dm

utils table manipulation methods for zoomed_dm objects

Description

Extract the first or last rows from a table. Use these methods without the '.zoomed_dm' suffix (see examples). The methods for regular dm objects extract the first or last tables.

Usage

## S3 method for class 'zoomed_dm'
head(x, n = 6L, ...)

## S3 method for class 'zoomed_dm'
tail(x, n = 6L, ...)
Arguments

\(x\)  object of class zoomed_dm

\(n\)  an integer vector of length up to \(\text{dim}(x)\) (or 1, for non-dimensioned objects). Values specify the indices to be selected in the corresponding dimension (or along the length) of the object. A positive value of \(n[i]\) includes the first/last \(n[i]\) indices in that dimension, while a negative value excludes the last/first \(\text{abs}(n[i])\), including all remaining indices. NA or non-specified values (when \(\text{length}(n) < \text{length}(\text{dim}(x))\)) select all indices in that dimension. Must contain at least one non-missing value.

... arguments to be passed to or from other methods.

Details

see manual for the corresponding functions in \texttt{utils}.

Value

A zoomed_dm object.

Examples

```r
zoomed <- dm_nycflights13() %>%
  dm_zoom_to(flights) %>%
  head(4)
zoomed
dm_insert_zoomed(zoomed, new_tbl_name = "head_flights")
```

materialize  \hspace{1cm} Materialize

Description

compute() materializes all tables in a \texttt{dm} to new (temporary or permanent) tables on the database. collect() downloads the tables in a \texttt{dm} object as local \texttt{tibbles}.

Usage

```r
## S3 method for class 'dm'
compute(x, ...)

## S3 method for class 'dm'
collect(x, ..., progress = NA)
```
Arguments

x  A dm.

... Passed on to compute().

progress Whether to display a progress bar, if NA (the default) hide in non-interactive mode, show in interactive mode. Requires the 'progress' package.

Details

Called on a dm object, these methods create a copy of all tables in the dm. Depending on the size of your data this may take a long time.

Value

A dm object of the same structure as the input.

Examples

```r
financial <- dm_financial_sqlite()

financial %>%
  pull_tbl(districts) %>%
  dbplyr::remote_name()

# compute() copies the data to new tables:
financial %>%
  compute() %>%
  pull_tbl(districts) %>%
  dbplyr::remote_name()

# collect() returns a local dm:
financial %>%
  collect() %>%
  pull_tbl(districts) %>%
class()
```

Description

This function has methods for both dm classes:

1. With `pull_tbl.dm()` you can chose which table of the dm you want to retrieve.
2. With `pull_tbl.zoomed_dm()` you will retrieve the zoomed table in the current state.
Usage

pull_tbl(dm, table)

Arguments

dm
A dm object.

table
One unquoted table name for pull_tbl.dm(), ignored for pull_tbl.zoomed_dm().

Value

The requested table

Examples

# For an unzoomed dm you need to specify the table to pull:
dm_nycflights13() %>%
pull_tbl(airports)

# If zoomed, pulling detaches the zoomed table from the dm:
dm_nycflights13() %>%
dm_zoom_to(airports) %>%
pull_tbl()

reunite_parent_child  Merge two tables that are linked by a foreign key relation

Description

[Questioning]
Perform table fusion by combining two tables by a common (key) column, and then removing this column.

reunite_parent_child(): After joining the two tables by the column id_column, this column will be removed. The transformation is roughly the inverse of what decompose_table() does.

reunite_parent_child_from_list(): After joining the two tables by the column id_column, id_column is removed.

This function is almost exactly the inverse of decompose_table() (the order of the columns is not retained, and the original row names are lost).

Usage

reunite_parent_child(child_table, parent_table, id_column)

reunite_parent_child_from_list(list_of_parent_child_tables, id_column)
Arguments

child_table  Table (possibly created by decompose_table()) that references parent_table
parent_table  Table (possibly created by decompose_table()).
id_column    Identical name of referencing/referenced column in child_table/parent_table.
list_of_parent_child_tables
            Cf arguments child_table and parent_table from reunite_parent_child(), but both in a named list (as created by decompose_table()).

Value

A wide table produced by joining the two given tables.

Life cycle

These functions are marked “questioning” because they feel more useful when applied to a table in a dm object.

See Also

Other table surgery functions: decompose_table()

Examples

decomposed_table <- decompose_table(mtcars, new_id, am, gear, carb)
ct <- decomposed_table$child_table
pt <- decomposed_table$parent_table

reunite_parent_child(ct, pt, new_id)
reunite_parent_child_from_list(decomposed_table, new_id)

Description

[Experimental]

These methods provide a framework for manipulating individual rows in existing tables. All operations expect that both existing and new data are presented in two compatible tbl objects.

If y lives on a different data source than x, it can be copied automatically by setting copy = TRUE, just like for dplyr::left_join().

On mutable backends like databases, these operations manipulate the underlying storage. In contrast to all other operations, these operations may lead to irreversible changes to the underlying database. Therefore, in-place updates must be requested explicitly with in_place = TRUE. By default, an informative message is given. Unlike compute() or copy_to(), no new tables are created.

The sql_rows_*() functions return the SQL used for the corresponding rows_*() function with in_place = FALSE. y needs to be located on the same data source as x.
sql_returning_cols() and sql_output_cols() construct the SQL required to support the returning argument. Two methods are required, because the syntax for SQL Server (and some other databases) is vastly different from Postgres and other more standardized DBs.

Usage

```r
## S3 method for class 'tbl_dbi'
rows_insert(
  x,
  y,
  by = NULL,
  ...,
  in_place = NULL,
  copy = FALSE,
  check = NULL,
  returning = NULL
)

## S3 method for class 'tbl_dbi'
rows_update(
  x,
  y,

  in_place = NULL,
  copy = FALSE,
  check = NULL,
  returning = NULL
)

sql_rows_insert(x, y, ..., returning_cols = NULL)

sql_rows_update(x, y, by, ..., returning_cols = NULL)

sql_rows_patch(x, y, by, ..., returning_cols = NULL)

sql_rows_delete(x, y, by, ..., returning_cols = NULL)

sql_returning_cols(x, returning_cols, ...)

sql_output_cols(x, returning_cols, output_delete = FALSE, ...)

Arguments

x A pair of data frames or data frame extensions (e.g. a tibble). y must have the same columns of x or a subset.
y A pair of data frames or data frame extensions (e.g. a tibble). y must have the same columns of x or a subset.
by An unnamed character vector giving the key columns. The key values must uniquely identify each row (i.e. each combination of key values occurs at most once), and the key columns must exist in both x and y.

By default, we use the first column in y, since the first column is a reasonable place to put an identifier variable.

... Other parameters passed onto methods.
in_place Should x be modified in place? This argument is only relevant for mutable backends (e.g. databases, data.tables).

When TRUE, a modified version of x is returned invisibly; when FALSE, a new object representing the resulting changes is returned.
copy If x and y are not from the same data source, and copy is TRUE, then y will be copied into the same src as x. This allows you to join tables across srcs, but it is a potentially expensive operation so you must opt into it.
check
Set to TRUE to always check keys, or FALSE to never check. The default is to check only if in_place is TRUE or NULL. Currently these checks are no-ops and need yet to be implemented.

returning
[Experimental] <tidy-select> Columns to return of the inserted data. Note that also columns not in y but automatically created when inserting into x can be returned, for example the id column. Due to upstream limitations, a warning is given if this argument is passed unquoted. To avoid the warning, quote the argument manually: use e.g. returning = quote(everything())

returning_cols
A character vector of unquote column names to return, created from the returning argument. Methods for database that do not support this should raise an error.

output_delete
For sql_output_cols(), construct the SQL for a DELETE operation.

Value
A tbl object of the same structure as x. If in_place = TRUE, the underlying data is updated as a side effect, and x is returned, invisibly. If return columns are specified with returning then the resulting tibble is stored in the attribute returned_rows. This can be accessed with get_returned_rows().

Examples

```r
data <- dbplyr::memdb_frame(a = 1:3, b = letters[c(1:2, NA)], c = 0.5 + 0:2)
data
try(rows_insert(data, tibble::tibble(a = 4, b = "z")))
rows_insert(data, tibble::tibble(a = 4, b = "z"), copy = TRUE)
rows_update(data, tibble::tibble(a = 2:3, b = "w"), copy = TRUE, in_place = FALSE)
rows_patch(data, dbplyr::memdb_frame(a = 1:4, c = 0), in_place = FALSE)
rows_insert(data, dbplyr::memdb_frame(a = 4, b = "z"), in_place = TRUE)
rows_update(data, dbplyr::memdb_frame(a = 2:3, b = "w"), in_place = TRUE)
rows_patch(data, dbplyr::memdb_frame(a = 1:4, c = 0), in_place = TRUE)
data
```
The functions make sure that the tables in the target dm are processed in topological order so that parent (dimension) tables receive insertions before child (fact) tables.

These operations, in contrast to all other operations, may lead to irreversible changes to the underlying database. Therefore, in-place operation must be requested explicitly with `in_place = TRUE`. By default, an informative message is given.

dm_rows_insert() adds new records via `rows_insert()`. The primary keys must differ from existing records. This must be ensured by the caller and might be checked by the underlying database. Use `in_place = FALSE` and apply `dm_examine_constraints()` to check beforehand.

dm_rows_update() updates existing records via `rows_update()`. Primary keys must match for all records to be updated.

dm_rows_patch() updates missing values in existing records via `rows_patch()`. Primary keys must match for all records to be patched.

dm_rows_upsert() updates existing records and adds new records, based on the primary key, via `rows_upsert()`.

dm_rows_delete() removes matching records via `rows_delete()`, based on the primary key. The order in which the tables are processed is reversed.

dm_rows_truncate() removes all records via `rows_truncate()`, only for tables in dm. The order in which the tables are processed is reversed.

Usage

```r
dm_rows_insert(x, y, ..., in_place = NULL, progress = NA)
dm_rows_update(x, y, ..., in_place = NULL, progress = NA)
dm_rows_patch(x, y, ..., in_place = NULL, progress = NA)
dm_rows_upsert(x, y, ..., in_place = NULL, progress = NA)
dm_rows_delete(x, y, ..., in_place = NULL, progress = NA)
dm_rows_truncate(x, y, ..., in_place = NULL, progress = NA)
```

Arguments

- **x**: Target dm object.
- **y**: dm object with new data.
- **...**: These dots are for future extensions and must be empty.
- **in_place**: Should x be modified in place? This argument is only relevant for mutable backends (e.g. databases, data.tables).
  
  When TRUE, a modified version of x is returned invisibly; when FALSE, a new object representing the resulting changes is returned.
- **progress**: Whether to display a progress bar, if NA (the default) hide in non-interactive mode, show in interactive mode. Requires the `progress` package.
Value

A dm object of the same dm_ptype() as x. If in_place = TRUE, the underlying data is updated as a side effect, and x is returned, invisibly.

Examples

# Establish database connection:
sqlite <- DBI::dbConnect(RSQLite::SQLite())

# Entire dataset with all dimension tables populated
# with flights and weather data truncated:
flights_init <-
  dm_nycflights13() %>%
  dm_zoom_to(flights) %>%
  filter(FALSE) %>%
  dm_update_zoomed() %>%
  dm_zoom_to(weather) %>%
  filter(FALSE) %>%
  dm_update_zoomed()

# Target database:
flights_sqlite <- copy_dm_to(sqlite, flights_init, temporary = FALSE)
print(dm_nrow(flights_sqlite))

# First update:
flights_jan <-
  dm_nycflights13() %>%
  dm_select_tbl(flights, weather) %>%
  dm_zoom_to(flights) %>%
  filter(month == 1) %>%
  dm_update_zoomed() %>%
  dm_zoom_to(weather) %>%
  filter(month == 1) %>%
  dm_update_zoomed()
print(dm_nrow(flights_jan))

# Copy to temporary tables on the target database:
flights_jan_sqlite <- copy_dm_to(sqlite, flights_jan)

# Dry run by default:
dm_rows_insert(flights_sqlite, flights_jan_sqlite)
print(dm_nrow(flights_sqlite))

# Explicitly request persistence:
dm_rows_insert(flights_sqlite, flights_jan_sqlite, in_place = TRUE)
print(dm_nrow(flights_sqlite))

# Second update:
flights_feb <-
  dm_nycflights13() %>%
  dm_select_tbl(flights, weather) %>%
# Copy to temporary tables on the target database:
flights_feb_sqlite <- copy_dm_to(sqlite, flights_feb)

# Explicit dry run:
flights_new <- dm_rows_insert(
  flights_sqlite,
  flights_feb_sqlite,
  in_place = FALSE
)
print(dm_nrow(flights_new))
print(dm_nrow(flights_sqlite))

# Check for consistency before applying:
flights_new %>%
  dm_examine_constraints()

# Apply:
dm_rows_insert(flights_sqlite, flights_feb_sqlite, in_place = TRUE)
print(dm_nrow(flights_sqlite))

DBI::dbDisconnect(sqlite)

---

rows_truncate

**Truncate all rows**

**Description**

`rows_truncate()` removes all rows. This operation corresponds to TRUNCATE in SQL. ... is ignored.

**Usage**

`rows_truncate(x, ..., in_place = FALSE)`

`sql_rows_truncate(x, ...)`

**Arguments**

- `x` A data frame or data frame extension (e.g. a tibble).
- `...` Other parameters passed onto methods.
Should x be modified in place? This argument is only relevant for mutable backends (e.g. databases, data.tables). When TRUE, a modified version of x is returned invisibly; when FALSE, a new object representing the resulting changes is returned.

Description

Use these methods without the `.zoomed_dm` suffix (see examples).

Usage

```r
## S3 method for class 'zoomed_dm'
unite(data, col, ..., sep = "_", remove = TRUE, na.rm = FALSE)

## S3 method for class 'zoomed_dm'
separate(data, col, into, sep = "[^[:alnum:]]+", remove = TRUE, ...)
```

Arguments

- `data`: object of class `zoomed_dm`
- `col`: For `unite.zoomed_dm`: see `tidyr::unite`
  For `separate.zoomed_dm`: see `tidyr::separate`
- `sep`: For `unite.zoomed_dm`: see `tidyr::unite`
  For `separate.zoomed_dm`: see `tidyr::separate`
- `remove`: For `unite.zoomed_dm`: see `tidyr::unite`
  For `separate.zoomed_dm`: see `tidyr::separate`
- `na.rm`: see `tidyr::unite`
- `into`: see `tidyr::separate`

Examples

```r
zoom_united <- dm_nycflights13() %>%
  dm_zoom_to(flights) %>%
  select(year, month, day) %>%
  unite("month_day", month, day)
zoom_united
zoom_united %>%
  separate(month_day, c("month", "day"))
```
