Package ‘ergmito’

February 12, 2020

Version 0.2-1
Date 2020-02-10
Title Exponential Random Graph Models for Small Networks
Description Simulation and estimation of Exponential Random Graph Models (ERGMs) for small networks using exact statistics. As a difference from the ‘ergm’ package, ‘ergmito’ circumvents using Markov-Chain Maximum Likelihood Estimator (MC-MLE) and instead uses Maximum Likelihood Estimator (MLE) to fit ERGMs for small networks. As exhaustive enumeration is computationally feasible for small networks, this R package takes advantage of this and provides tools for calculating likelihood functions, and other relevant functions, directly, meaning that in many cases both estimation and simulation of ERGMs for small networks can be faster and more accurate than simulation-based algorithms.

**as_adjmat**

*An alternative to as.matrix to retrieve adjacency matrix fast*

**Description**

This function does not perform significant checks. Furthermore, this function won't keep the row/col names.

**Usage**

```r
as_adjmat(x)
```

## S3 method for class 'network'

```r
as_adjmat(x)
```

## S3 method for class 'matrix'

```r
as_adjmat(x)
```

## S3 method for class 'list'

```r
as_adjmat(x)
```

## S3 method for class 'formula'

```r
as_adjmat(x)
```

**Arguments**

- **x**
  
  An object to be coerced as an adjacency matrix.

---

**blockdiagonalize**

*Block-diagonal models using ergm*

**Description**

These two functions are used to go back and forth from a pooled ergm vs a blockdiagonal model, the latter to be fitted using `ergm::ergm`.

**Usage**

```r
blockdiagonalize(x, attrname = "block")
```

```r
splitnetwork(x, attrname)
```

```r
ergm_blockdiag(formula, ...)
```
check_support

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>x</td>
<td>In the case of blockdiagonalize, a list of networks or matrices. For splitnetwork a single network object with a vertex attribute that can be used to split the data.</td>
</tr>
<tr>
<td>attrname</td>
<td>Name of the attribute that holds the block ids.</td>
</tr>
<tr>
<td>formula</td>
<td>An ergm model which networks’ will be wrapped with blockdiagonalize (see details).</td>
</tr>
<tr>
<td>...</td>
<td>Further arguments passed to the method.</td>
</tr>
</tbody>
</table>

Details

The function `ergm_blockdiag` is a wrapper function that takes the model’s network, stacks the networks into a single block diagonal net, and calls `ergm::ergm` with the option `constraints = blockdiag("block")`. One side effect of this function is that it loads the `ergm` package via `requireNamespace`, so after executing the function `ergm` the package will be loaded.

Value

An object of class `ergm::ergm`.

Examples

```r
library(ergm)
data(fivenets)

fivenets2 <- blockdiagonalize(fivenets, attrname = "block")  # A network with
ans0 <- ergm(
  fivenets2 ~ edges + nodematch("female"),
  constraints = ~blockdiag("block")
)
ans1 <- ergmito(fivenets ~ edges + nodematch("female"))

# This is equivalent
ans2 <- ergm_blockdiag(fivenets ~ edges + nodematch("female"))
```

check_support

Check the convergence of ergmito estimates

Description

This is an internal function used to check the convergence of the optim function.

Usage

```r
check_support(target.stats, stats.statmat, threshold = 0.8, warn = TRUE)
check_convergence(optim_output, model, support, crit = 5)
```
**check_support**

**Arguments**

- `target.stats`, `stats.statmat`
  
  See `ergmito_formulae`.

- `threshold` Numeric scalar. Confidence range for flagging an observed statistic as potentially near the boundary.

- `warn` logical scalar.

- `optim_output` A list output from the `stats::optim` function.

- `model` An object of class `ergmito_loglik`.

- `support` As returned by `check_support`.

- `crit` Numeric scalar. Level at which a parameter estimate will be questioned.

**Value**

A list with the following components:

- `par` Updated set of parameters
- `vcov` Updated variance-covariance matrix
- `valid` Vector of integers with the parameters that are marked as OK.
- `status` Return code of the analysis. See details.
- `note` A note describing the status.

**Return codes**

The function makes an analysis of the outcome of the model and makes the corresponding adjustments when required. In particular, we check:

1. Whether the optimization algorithm converged or not
2. If the obtained estimates maximize the function. If this is not the case, the function checks whether the MLE may not exist. This usually happens when the log-likelihood function can improve by making increments to parameters that are already tagged as large. If the ll improves, then the value is replaced with `Inf` (+- depending on the sign of the parameter).
3. If the Hessian is semi-positive-definite, i.e. if it is invertible. If it is not, it usually means that the function did not converged, in which case we will use `MASS::ginv` instead.

The return codes are composed of two numbers, the first number gives information regarding of the parameter estimates, while the second number give information about the variance-covariance matrix.

**Column 1:**

- 0: Converged and estimates at the max.
- 1: It did not converged, but I see no issue in the max.
- 2: One or more estimates went to +/-Inf
- 3: All went to hell. All estimates went to +/-Inf

**Column 2:**
• 0: Hessian is p.s.d.
• 1: Hessian is not p.s.d.

Possible codes and corresponding messages:
• 00 All OK (no message).
• 01 optim converged, but the Hessian is not p.s.d.. % Convergence, but the hessian is not psd
• 10 optim did not converged, but the estimates look OK.. % Optim did not reported convergence, but things look OK.
• 11 optim did not converged, and the Hessian is not p.s.d.. % Optim did not converged, but the hessian is not psd.
• 20 A subset of the parameters estimates was replaced with +/-Inf.. % One or more estimates went to inf, all finite were able to be inverted.
• 21 A subset of the parameters estimates was replaced with +/-Inf, and the Hessian matrix is not p.s.d.. % One or more are inf, hessian is not psd
• 30 All parameters went to +/-Inf suggesting that the MLE may not exists.. % All estimates went to Inf (degenerate distribution).

---

**count_stats**  
**Count Network Statistics**

**Description**

This function is similar to what `ergm::summary_formula` does, but it provides a fast wrapper suited for matrix class objects.

**Usage**

```r
count_stats(X, ...)  
AVAILABLE_STATS()
```

```r
## S3 method for class 'formula'
count_stats(X, ...)
```

```r
## S3 method for class 'list'
count_stats(X, terms, attrs = NULL, ...)
```

**Arguments**

- **X**: List of square matrices. (networks)
- **...**: Passed to the method.
- **terms**: Character vector with the names of the statistics to calculate. Currently, the only available statistics are: 'mutual', 'edges', 'triad', 'crease', 'ctriple', 'nodeicov', 'nodeocov', 'nodematch', 'triangle', 'balance', 't300', 't102', 'absdiff', 'idegree1.5', 'odegree1.5', 'ostar1', 'ostar2', 'ostar3', 'ostar4', 'istar1', 'istar2', 'istar3', 'istar4'.
- **attrs**: A list of vectors. This is used when term has a nodal attribute such as `nodeicov(atrname="")`. 
ergmito

Value

A matrix of size length(X) * length(terms) with the corresponding counts of statistics.

Examples

# DGP
x <- powerset(5)
ans0 <- count_stats(x[1:20], c("mutual", "edges"))

# Calculating using summary_formula
fm <- x[[i]] ~ mutual + edges
ans1 <- lapply(1:20, function(i) {
  environment(fm) <- environment()
  ergm::summary_formula(fm)
})

ans1 <- do.call(rbind, ans1)

# Comparing
all.equal(unname(ans0), unname(ans1))

---

ergmito  Estimation of ERGMs using Maximum Likelihood Estimation (MLE)

Description

As a difference from ergm::ergm, ergmito uses the exact log-likelihood function for fitting the model. This implies that all the $2^{n*(n-1)}$ graphs are generated for computing the normalizing constant of the ERGM model. As a rule of thumb, directed graphs with more than 5 vertices should not be fitted using MLE, but instead MC-MLE as implemented in the ergm package. The same applies for un-directed graphs with more than 8 vertices.

Usage

ergmito(
  model,
  gattr_model = NULL,
  stats.weights = NULL,
  stats.statmat = NULL,
  optim.args = list(),
  init = NULL,
  use.grad = TRUE,
  target.stats = NULL,
  ntries = 1L,
  keep.stats = TRUE,
  ...
)
## S3 method for class 'ergmito'
print(x, ...)

## S3 method for class 'ergmito'
summary(object, ...)

## S3 method for class 'ergmito_summary'
print(x, ...)

## S3 method for class 'ergmito'
coef(object, ...)

## S3 method for class 'ergmito'
logLik(object, ...)

## S3 method for class 'ergmito'
nobs(object, ...)

## S3 method for class 'ergmito'
vcov(object, solver = NULL, ...)

## S3 method for class 'ergmito'
formula(x, ...)

### Arguments

- **model**
  - Model to estimate. See `ergm::ergm`. The only difference with `ergm` is that the LHS can be a list of networks.

- **gattr_model**
  - A formula. Model specification for graph attributes. This is useful when using multiple networks.

- **stats.weights**
  - Either an integer vector or a list of integer vectors (see `exact_loglik`).

- **stats.statmat**
  - Either a matrix or a list of matrices (see `exact_loglik`).

- **optim.args**
  - List. Passed to `stats::optim`.

- **init**
  - A numeric vector. Sets the starting parameters for the optimization routine. Default is a vector of zeros.

- **use.grad**
  - Logical. When `TRUE` passes the gradient function to `optim`. This is intended for testing only (internal use).

- **target.stats**
  - A matrix of target statistics (see `ergm::ergm`).

- **ntries**
  - Integer scalar. Number of tries to estimate the MLE (see details).

- **keep.stats**
  - Logical scalar. When `TRUE` (the default), the matrices and vectors associated with the sufficient statistics will be returned. Otherwise the function discards them. This may be useful for saving memory space when estimating multiple models.

- **...**
  - Further arguments passed to the method. In the case of `ergmito`, ... are passed to `ergmito_formulae`. 
x, object An object of class ergmito

solver Function. Used to compute the inverse of the hessian matrix. When not null, the variance-covariance matrix is recomputed using that function. By default, ergmito uses MASS::ginv.

Value

An list of class ergmito:

- call The program call.
- coef Named vector. Parameter estimates.
- iterations Integer. Number of times the log-likelihood was evaluated (see stats::optim).
- mle.lik Numeric. Final value of the objective function.
- null.lik Numeric. Final value of the objective function for the null model.
- covar Square matrix of size \(\text{length}(\text{coef})\). Variance-covariance matrix computed using the exact hessian as implemented in exact_hessian.
- coef.init Named vector of length \(\text{length}(\text{coef})\). Initial set of parameters used in the optimization.
- formulae An object of class ergmito_loglik.
- nobs Integer scalar. Number of networks in the model.
- network Networks passed via model.
- optim.out, optim.args Results from the optim call and arguments passed to it.
- status, note Convergence code. See check_convergence
- best_try Integer scalar. Index of the run with the highest log-likelihood value.
- history Matrix of size \(\text{ntries} \times (k + 1)\). History of the parameter estimates and the reached log-likelihood values.
- timer Vector of times (for benchmarking). Each unit marks the starting point of the step.

MLE

Maximum Likelihood Estimates are obtained using the stats::optim function. The default method for maximization is BFGS using both the log-likelihood function and its corresponding gradient.

Another important factor to consider is the existence of the MLE estimates As shown in Handcock (2003), if the observed statistics are near the border if the support function (e.g. too many edges or almost none), then, even if the MLE estimates exists, the optimization function may not be able to reach the optima. Moreover, if the target (observed) statistics live in the boundary, then the MLE estimates do not exists. In general, this should not be an issue in the context of the pooled model, as the variability of observed statistics should be enough to avoid those situations.

The function ergmito will try to identify possible cases of non-existence, of the MLE, and if identified then try to re estimate the model parameters using larger values than the ones obtained, if the log-likelihood is greater, then it is assumed that the model is degenerate and the corresponding values will be replaced with either +\(\text{Inf}\) or -\(\text{Inf}\). By default, this behavior is checked anytime that the absolute value of the estimates is greater than 5, or the sufficient statistics were flagged as potentially outside of the interior of the support (close to zero or to its max).
In the case of `ntries`, the optimization is repeated that number of times, each time perturbing the `init` parameter by adding a Normally distributed vector. The result which reaches the highest log-likelihood will be the one reported as parameter estimates. This feature is intended for testing only. Anecdotally, `optim` reaches the max in the first try.

**See Also**

The function `plot.ergmito` for post-estimation diagnostics.

**Examples**

```r
# Generating a small graph
set.seed(12)
n <- 4
net <- rbernoulli(n, p = .7)
model <- net ~ edges + mutual

library(ergm)
ans_ergmito <- ergmito(model)
ans_ergm <- ergm(model)

# The ergmito should have a larger value
ergm.exact(ans_ergmito$coef, model)
ergm.exact(ans_ergm$coef, model)

summary(ans_ergmito)
summary(ans_ergm)

# Example 2: Estimating an ERGMito using data with know DGP parameters
# data(fivenets)

model1 <- ergmito(fivenets ~ edges + nodematch("female"))
summary(model1) # This data has know parameters equal to -2.0 and 2.0

# Example 3: Likelihood ratio test using the lmtest R package
if (require(lmtest)) {
  data(fivenets)
  model1 <- ergmito(fivenets ~ edges + nodematch("female"))
  model2 <- ergmito(fivenets ~ edges + nodematch("female") + mutual)

  lrtest(model1, model2)
  # Likelihood ratio test
  #
  # Model 1: fivenets ~ edges + nodematch("female")
  # Model 2: fivenets ~ edges + nodematch("female") + mutual
  # # Df LogLik Df Chisq Pr(>Chisq)
  # 1 2  -34.671
  # 2 3  -34.205 1  0.9312 0.3346
}
```
Description

Bootstrap of ergmito

Usage

ergmito_boot(x, ..., R, ncpus = 1L, cl = NULL)

## S3 method for class 'formula'
ergmito_boot(x, ..., R, ncpus = 1L, cl = NULL)

## S3 method for class 'ergmito'
ergmito_boot(x, ..., R, ncpus = 1L, cl = NULL)

## S3 method for class 'ergmito_boot'
print(x, ...)

Arguments

x Either a formula or an object of class ergmito.
...

Additional arguments passed to the method.
R

Integer. Number of replicates
cpus

Integer Number of CPUs to use.
cl

An object of class cluster (see parallel::makePSOCKcluster)

Details

The resulting sample of parameters estimates is then used to compute the variance-covariance matrix of the model. Cases in which Inf/NaN/NA values were returned are excluded from the calculation.

Value

An object of class ergmito_boot and ergmito

Examples

# Simulating 20 bernoulli networks of size 4
nets <- replicate(20, rbernoulli(4), simplify = FALSE)
ergmito_formulae  Processing formulas in ergmito

Description

Analyze formula objects returning the matrices of weights and sufficient statistics to be used in the model together with the log-likelihood and gradient functions for joint models.

Usage

```r
ergmito_formulae(
  model,
  gattr_model = NULL,
  target.stats = NULL,
  stats.weights = NULL,
  stats.statmat = NULL,
  env = parent.frame(),
  ...
)
```

Arguments

- `model` A formula. The left-hand-side can be either a small network, or a list of networks.
- `gattr_model` A formula. Model specification for graph attributes. This is useful when using multiple networks.
- `target.stats` Observed statistics. If multiple networks, then a list, otherwise a named vector (see `ergm::summary_formula`).
- `stats.weights`, `stats.statmat` Lists of sufficient statistics and their respective weights.
- `env` Environment in which `model` should be evaluated.
- `...` Further arguments passed to `ergm::ergm.allstats`.

Value

A list of class `ergmito_loglik`.

- `loglik` A function. The log-likelihood function.
- `grad` A function. The gradient of the model.
- `stats.weights`, `stats.statmat` two list of objects as returned by `ergm::ergm.allstats`.
- `model` A formula. The model passed.
- `npars` Integer. Number of parameters.
- `nnets` Integer. Number of networks in the model.
- `vertex.attr` Character vector. Vertex attributes used in the model.
- `term.names` Names of the terms used in the model.
Examples

```r
data(fivenets)
model <- ergmito_formulae(fivenets ~ edges + nodematch("female"))
pred(model)
model$loglik(c(-2, 2))
```

Description

Goodness of Fit diagnostics for ERGMito models

Usage

```r
gof_ergmito(
  object,
  GOF = NULL,
  probs = c(0.05, 0.95),
  sim_ci = FALSE,
  R = 50000L,
  ncores = 1L,
  ...
)
```

## S3 method for class 'ergmito_gof'
print(x, digits = 2L, ...)

## S3 method for class 'ergmito_gof'
plot(
  x,
  y = NULL,
  main = NULL,
  sub = NULL,
  tnames = NULL,
  sort_by_ci = FALSE,
  ...
)
```

Arguments

- **object**: An object of class \texttt{ergmito}.
- **GOF**: Formula. Additional set of parameters to perform the GOF.
- **probs**: Numeric vector. Quantiles to plot (see details).
- **sim_ci**: Logical scalar. If \texttt{FALSE}, the default, it will compute the quantiles analytically, otherwise it samples from the ERGM distribution.
R Integer scalar. Number of simulations to generate (passed to sample). This is only used if sim.ci = TRUE.

ncores Integer scalar. Number of cores to use for parallel computations (currently ignored).

... Further arguments passed to stats::quantile.

x An object of class ergmito_gof.

digits Number of digits to used when printing

y Ignored.

main, sub Title and subtitle of the plot (see graphics::title).

tnames A named character vector. Alternative names for the terms.

sort_by_ci Logical scalar. When TRUE it will sort the x-axis by the with of the CI in for the first parameter of the model.

Details

The Goodness of Fit function uses the fitted ERGMito to calculate a given confidence interval for a set of sufficient statistics. By default (and currently the only available option), this is done on the sufficient statistics specified in the model.

In detail, the algorithm is executed as follow:

For every network in the list of networks do:

1. Calculate the probability of observing each possible graph in its support using the fitted model.

2. If sim.ci = TRUE, draw R samples from each set of parameters using the probabilities computed. Then using the quantile function, calculate the desired quantiles of the sufficient statistics. Otherwise, compute the quantiles using the analytic quantiles using the full distribution.'

The plot method is particularly convenient since it graphically shows whether the target statistics of the model (observed statistics) fall within the simulated range.

The print method tries to copy (explicitly) the print method of the gof function from the ergm R package.

Value

An object of class ergmito_gof. This is a list with the following components:

- ci A list of matrices of length nnets(object) with the corresponding confidence intervals for the statistics of the model.
- target.stats A matrix of the target statistics.
- ergmito.probs A list of numeric vectors of length nnets(object) with the probabilities associated to each possible structure of network.
- probs The value passed via probs.
- model The fitted model.
- term.names Character vector. Names of the terms used in the model.
- quantile.args A list of the values passed via . . .
**exact_loglik**

### Examples

```r
# Fitting the fivenets model
data(fivenets, package = "ergmito")
fit <- ergmito(fivenets ~ edges + nodematch("female"))

# Calculating the gof
ans <- gof_ergmito(fit)

# Looking at the results
ans
plot(ans)
```

### Description

This function can be compared to `ergm::ergm.exact` with the statistics not centered at \( x \), the vector of observed statistics.

### Usage

```r
exact_loglik(x, params, ...)  # S3 method for class 'ergmito_ptr'
exact_loglik(x, params, ...)  # Default S3 method:
exact_gradient(x, params, ...)  # S3 method for class 'ergmito_ptr'
exact_gradient(x, params, ...)  # Default S3 method:
exact_hessian(x, params, stats.weights, stats.statmat)
```

### Arguments

- **x**  
  Matrix. Observed statistics
- **params**  
  Numeric vector. Parameter values of the model.
- **...**  
  Arguments passed to the default methods.
- **stats.weights**  
  Either an integer vector or a list of integer vectors (see `exact_loglik`).
- **stats.statmat**  
  Either a matrix or a list of matrices (see `exact_loglik`).
**Sufficient statistics**

One of the most important components of ergmito is calculating the full support of the model’s sufficient statistics. Right now, the package uses the function `ergm::ergm.allstats` which returns a list of two objects:

- **weights**: An integer vector of counts.
- **statmat**: A numeric matrix with the rows as unique vectors of sufficient statistics.

Since ergmito can vectorize operations, in order to specify weights and statistics matrices for each network in the model, the user needs to pass two lists `stats.weights` and `stats.statmat`. While both lists have to have the same length (since its elements are matched), this needs not to be the case with the networks, as the user can specify a single set of weights and statistics that will be recycled (smartly).

**Examples**

```r
data(fivenets)
ans <- ergmito(fivenets ~ edges + nodematch("female"))

# This computes the likelihood for all the networks independently
with(ans$formulae, {
  exact_loglik(
    x = target.stats,
    params = coef(ans),
    stats.weights = stats.weights,
    stats.statmat = stats.statmat
  )
})

# This should be close to zero
with(ans$formulae, {
  exact_gradient(
    x = target.stats,
    params = coef(ans),
    stats.weights = stats.weights,
    stats.statmat = stats.statmat
  )
})

# Finally, the hessian
with(ans$formulae, {
  exact_hessian(
    x = target.stats,
    params = coef(ans),
    stats.weights = stats.weights,
    stats.statmat = stats.statmat
  )
})
```
**extract.ergmito**

*Extract function to be used with the texreg package.*

---

**Description**

To be used with the `texreg` package. This function can be used to generate nice looking tables of ERGMitos estimates.

**Usage**

```r
extract.ergmito(
  model,
  include.aic = TRUE,
  include.bic = TRUE,
  include.loglik = TRUE,
  include.nnets = TRUE,
  include.convergence = TRUE,
  ...)
```

**Arguments**

- `model` An object of class `ergmito`.
- `include.aic`, `include.bic`, `include.loglik`
  - See `texreg::extract`.
- `include.nnets` Logical. When true, it adds the Number of networks used to the list of gof statistics. This can be useful when running pooled models.
- `include.convergence` Logical. When true, it adds the convergence value of the `stats::optim` function (0 means convergence).
- `...` Further arguments passed to `summary.ergmito`.

**Examples**

```r
library(texreg)
data(fivenets)
ans <- ergmito(fivenets ~ edges + nodematch("female"))
screenreg(ans)
```
fivenets  
Example of a group of small networks

Description
This list of networks was generated using the new_rergmito sampler from a set of 5 baseline networks with a random vector of female. The sufficient statistics that generate this data are edges and nodematch("female") with parameters -2.0 and 2.0 respectively.

Usage
fivenets

Format
An object of class list of length 5.

gedesic  
Geodesic distance matrix (all pairs)

Description
Calculates the shortest path between all pairs of vertices in a network. This uses the power matrices to do so, which makes it efficient only for small networks.

Usage
gedesic(x, force = FALSE, ...)  
geodesita(x, force = FALSE, ...)  
## S3 method for class 'list'  
geodesic(x, force = FALSE, ...)  
## S3 method for class 'matrix'  
geodesic(x, force = FALSE, simplify = FALSE, ...)  
## S3 method for class 'network'  
geodesic(x, force = FALSE, simplify = FALSE, ...)
**induced_submat**

**Arguments**

- **x**
  Either a list of networks (or square integer matrices), an integer matrix, a network, or an ergmito.

- **force**
  Logical scalar. If `force = FALSE` (the default) and `nvertex(x) > 100` it returns with an error. To force computation use `force = TRUE`.

- **...**
  Further arguments passed to the method.

- **simplify**
  Logical scalar. When TRUE it returns a matrix, otherwise, a list of length `nnets(x)`.

**Examples**

data(fivenets)
geodesic(fivenets)

---

**induced_submat** Extract a submatrix from a network

**Description**

This is similar to `network::get.inducedSubgraph`. The main difference is that the resulting object will always be a list of matrices, and it is vectorized.

**Usage**

```r
induced_submat(x, v, ...)  
```

### S3 method for class 'list'

```r
induced_submat(x, v, ...)
```

### S3 method for class 'network'

```r
induced_submat(x, v, ...)
```

### S3 method for class 'matrix'

```r
induced_submat(x, v, ...)
```

**Arguments**

- **x**
  Either a list or single matrices or network objects.

- **v**
  Either a list or a single integer vector of vertices to subset.

- **...**
  Currently ignored.
Details

Depending on the lengths of `x` and `v`, the function can take the following strategies:

- If both are of the same size, then it will match the networks and the vector of indices.
- If `length(x) == 1`, then it will use that single network as a baseline for generating the subgraphs.
- If `length(v) == 1`, then it will generate the subgraph using the same set of vertices for each network.
- If both have more than one element, but different sizes, then the function returns with an error.

Value

A list of matrices as a result of the subsetting.

Examples

```r
x <- rbernoulli(100)
induced_submat(x, c(1, 10, 30:50))

x <- rbernoulli(c(20, 20))
induced_submat(x, c(1:10))
```

matrix_to_network

Manipulation of network objects

Description

This function implements a vectorized version of `network::network::adjmat`. It allows us to turn regular matrices into network objects quickly.

Usage

```r
matrix_to_network(
  x,
  directed = rep(TRUE, length(x)),
  hyper = rep(FALSE, length(x)),
  loops = rep(FALSE, length(x)),
  multiple = rep(FALSE, length(x)),
  bipartite = rep(FALSE, length(x))
)
```

```r
## S3 method for class 'matrix'
matrix_to_network(
  x,
  directed = rep(TRUE, length(x)),
  hyper = rep(FALSE, length(x)),
)
## S3 method for class 'list'

```r
matrix_to_network(
  x,
  directed = rep(TRUE, length(x)),
  hyper = rep(FALSE, length(x)),
  loops = rep(FALSE, length(x)),
  multiple = rep(FALSE, length(x)),
  bipartite = rep(FALSE, length(x))
)
```

### Arguments
- `x`: Either a single square matrix (adjacency matrix), or a list of these.
- `directed`: Logical scalar, if FALSE then the function only checks the upper diagonal of the matrix assuming it is undirected.
- `hyper`, `multiple`, `bipartite`: Currently Ignored. Right now all the network objects created by this function set these parameters as FALSE.
- `loops`: Logical scalar. When FALSE (default) it will skip the diagonal of the adjacency matrix.

### Details
This version does not support adding the name parameter yet. The function in the network package includes the name of the vertices as an attribute.

Just like in the network function, NA are checked and added accordingly, i.e. if there is an NA in the matrix, then the value is recorded as a missing edge.

### Value
An object of class network. This is a list with the following elements:

- **mel Master Edge List**: A named list with length equal to the number of edges in the network. The list itself has 3 elements: `inl` (tail), `outl` (head), and `atl` (attribute). By default `atl`, a list itself, has a single element: `na`.
- **gal Graph Attributes List**: a named list with the following elements:
  - `n` Number of nodes
  - `mnext` Number of edges + 1
  - `directed,hyper,loops,multiple,bipartite` The arguments passed to the function.
- **val Vertex Attributes List**
- **iel In Edgest List**
- **oel Out Edgest List**
**new_ergmito_ptr**

**Examples**

```r
set.seed(155)
adjmats <- rbernoulli(rep(5, 20))
networks <- matrix_to_network(adjmats)
```

**Description**

After calculating the support of the sufficient statistics, the second most computationally expensive task is computing log-likelihoods, Gradients, and Hessian matrices of ERGMs. This function creates a pointer to an underlying class that is optimized to improve memory allocation and save computation time when possible.

**Usage**

```r
new_ergmito_ptr(target_stats, stats_weights, stats_statmat)
```

**Arguments**

- `target_stats`, `stats_weights`, `stats_statmat`
  
  see `exact_loglik`.

**Details**

This function is for internal used only. Non-advanced users are not encouraged to use it. See `ergmito_formulae` and `exact_loglik` for user friendly wrappers of this function.

**Recycling computations**

Some components of the likelihood, its gradient, and hessian can be pre-computed and recycled when needed. For example, it is usually the case that in optimization gradients are computed using a current state of the model’s parameter, which implies that the normalizing constant and some other matrix products will be the same between the log-likelihood and the gradient. Because of this, the underlying class `ergmito_ptr` will only re-calculate these shared components if the parameter used changes as well. This saves a significant amount of computation time.

**Scope of the class methods**

To save space, the class creates pointers to the matrices of sufficient statistics that the model uses. This means that once these objects are deleted the log-likelihood and the gradient functions become invalid from the computational point of view.
**new_rergmito**

---

**ERGMito sampler**

---

**Description**

Create a sampler object that allows you simulating streams of small networks fast.

**Usage**

```r
new_rergmito(
  model,
  theta = NULL,
  sizes = NULL,
  cl = NULL,
  ncores = 1L,
  force = FALSE,
  ...
)
```

## S3 method for class 'ergmito_sampler'

```r
x[i, j, ...]
```

## S3 method for class 'ergmito_sampler'

```r
print(x, ...)
```

**Arguments**

- `model` A formula.
- `theta` Named vector. Model parameters.
- `sizes` Integer vector. Values between 2 to 5 (6 becomes too intensive).
- `cl` An object of class `cluster`.
- `ncores` Integer. Number of processors to use.
- `force` Logical. When FALSE (default) will try to use ergmito’s stat count functions (see `count_stats`). This means that if one of the requested statistics in not available in ergmito, then we will use ergm to compute them, which is significantly slower (see details).
- `...` Further arguments passed to `ergm::ergm.allstats`.
- `x` An object of class `ergmito_sampler`.
- `i, j` `i` is an integer vector indicating the indexes of the networks to draw, while `j` the corresponding sizes. These need not to be of the same size.
Details

While the **ergm** package is very efficient, it was not built to do some of the computations required in the ergmito package. This translates in having some of the functions of the package (ergm) with poor speed performance. This led us to "reinvent the wheel" in some cases to speed things up, this includes calculating observed statistics in a list of networks.

The indexing method, [.ergmito_sampler, allows extracting networks directly by passing indexes. \(i\) indicates the index of the networks to draw, which go from 1 through \(2^{n*(n-1)}\), and \(j\) indicates the requested size.

Value

An environment with the following objects:

- `calc_prob` A function to calculate each graph’s probability under the specified model.
- `call` A language object with the call.
- `counts` A list with 3 elements: `stats` the sufficient statistics of each network, `weights` and `statmat` the overall matrices of sufficient statistics used to compute the likelihood.
- `network0` The baseline network used to either fit the model or obtain attributes.
- `networks` A list with the actual sample space of networks.
- `prob` A numeric
- `sample` A function to draw samples. \(n\) specifies the number of samples to draw, \(s\) the size of the networks, and `theta` the parameter to use to calculate the likelihoods.
- `theta` Named numeric vector with the current values of the model parameters.

The indexing method [.ergmito_sampler returns a named list of length `length(j)`.

Examples

```r
# We can generate a sampler from a random graph
set.seed(7131)
an <- new_rergmito(rbernoulli(4) ~ edges)

# Five samples
ans$sample(5, s = 4)

# or we can use some nodal data:
data(fivenets)
an <- new_rergmito(
    fivenets[[3]] ~ edges + nodematch("female"),
    theta = c(-1, 1)
)

# Five samples
ans$sample(5, s = 4) # All these networks have a "female" vertex attr
```
Utility functions to query network dimensions

**Description**

Utility functions to query network dimensions

**Usage**

```r
nvertex(x)

nedges(x, ...)
```

```r
## S3 method for class 'network'
nedges(x, ...)
```

```r
## S3 method for class 'list'
nedges(x, ...)
```

```r
## S3 method for class 'matrix'
nedges(x, ...)
```

```r
## S3 method for class 'ergmito'
nedges(x, ...)
```

```r
## S3 method for class 'formula'
nedges(x, ...)
```

```r
## S3 method for class 'network'
nvertex(x)
```

```r
## S3 method for class 'matrix'
nvertex(x)
```

```r
## S3 method for class 'list'
nvertex(x)
```

```r
## S3 method for class 'ergmito'
nvertex(x)
```

```r
## S3 method for class 'formula'
nvertex(x)
```

```r
nnets(x)
```

```r
## S3 method for class 'list'
nnets(x)
```
## S3 method for class 'matrix'
nnets(x)

## S3 method for class 'network'
nnets(x)

## S3 method for class 'ergmito'
nnets(x)

## S3 method for class 'formula'
nnets(x)

is_directed(x, check_type = FALSE)

## S3 method for class 'network'
is_directed(x, check_type = FALSE)

## S3 method for class 'list'
is_directed(x, check_type = FALSE)

## Default S3 method:
is_directed(x, check_type = FALSE)

## S3 method for class 'ergmito'
is_directed(x, check_type = FALSE)

## S3 method for class 'formula'
is_directed(x, check_type = FALSE)

### Arguments

- **x**: Either an object of class `ergmito`, `network`, `formula`, or `matrix`.
- **...**: Further arguments passed to the method. Currently only `nedges.network` receives arguments (see `network::network.edgecount`).
- **check_type**: Logical scalar. When checking for whether the network is directed or not, we can ask the function to return with an error if what we are checking is not an object of class `network`, otherwise it simply returns false.

### Value

`is_directed` checks whether the passed networks are directed using the function `network::is.directed`. In the case of multiple networks, the function returns a logical vector. Only objects of class `network` can be checked, otherwise, if `check_type = FALSE`, the function returns `TRUE` by default.

### Examples

```r
set.seed(771)
net <- lapply(rbernoulli(c(4, 4)), network::network, directed = FALSE)
```
is_directed(net)
is_directed(net[[1]])
is_directed(net - edges)

## Not run:
  is_directed(net[[1]][1:4, 1:4], check_type = TRUE) # Error

## End(Not run)
is_directed(net[[1]][1:4, 1:4])

plot.ergmito  

Function to visualize the optimization surface

Description

General diagnostics function. This function allows to visualize the surface to be maximize at around a particular point.

Usage

## S3 method for class 'ergmito'
plot(
  x,
  y = NULL,
  domain = NULL,
  plot. = TRUE,
  par_args = list(),
  image_args = list(),
  breaks = 50L,
  extension = 4L,
  params_labs = stats::setNames(names(coef(x)), names(coef(x))),
  ...
)

Arguments

x  An object of class ergmito.
y, ... Ignored.
domain  A list.
plot.  Logical. When TRUE (default), the function will call graphics::image and plot all possible combination of parameters.
par_args  Further arguments to be passed to graphics::par
image_args  Further arguments to be passed to graphics::image
breaks  Integer scalar. Number of splits per dimension.
extension  Numeric. Range value of the function.
params_labs  Named vector. Alternative labels for the parameters. It should be in the form of c("original name" = "new name").
Details

It calculates the surface coordinates for each pair of parameters included in the ERGMito.

Value

A list of length $\text{choose}(\text{length}(\text{object$coef}), 2)$ (all possible combinations of pairs of parameters), each with the following elements:

- z A matrix
- z A vector
- y A vector
- xlab A string. Name of the ERGM parameter in the x-axis.
- ylab A string. Name of the ERGM parameter in the y-axis.

The list is returned invisible.

See Also

The ergmito function.

Examples

```
set.seed(12)
x <- rbernoulli(c(4, 4, 5))
ans <- ergmito(x ~ edges + balance)
plot(ans)
```

---

**powerset**

*Power set of Directed Graphs of size n*

Description

Power set of Directed Graphs of size n

Usage

```
powerset(n, directed = TRUE, force = FALSE, chunk_size = 2e+05)
```
**Arguments**

- **n**: Integer. Number of edges.
- **directed**: Logical scalar. Whether to generate the power set of directed or undirected graphs.
- **force**: Logical scalar. When TRUE it generates the power set for n>5, otherwise it returns with error.
- **chunk_size**: Number of matrices to process at a time. If n = 5, then stack memory on the computer may overflow if chunk_size is relatively large.

**Examples**

- `powerset(2)`
- `powerset(4, directed = FALSE)`

**Description**

Takes an ergmito object and makes prediction at tie level. See details for information regarding its implementation.

**Usage**

```r
## S3 method for class 'ergmito'
predict(object, newdata = NULL, ...)
```

**Arguments**

- **object**: An object of class ergmito.
- **newdata**: New set of networks (or network) on which to make the prediction.
- **...**: Passed to `new_rergmito`, the workhorse of this method.

**Details**

After fitting a model with a small network (or a set of them), we can use the parameter estimates to calculate the likelihood of observing any given tie in the network, this is, the marginal probabilities at the tie level.

In particular, the function takes the full set of networks on the support of the model and adds them up weighted by the probability of observing them as predicted by the ERGM, formally:

\[
\hat{A} = \sum_i \Pr(A = a_i) \times a_i
\]

Where \( \hat{A} \) is the predicted adjacency matrix, and \( a_i \) is the i-th network in the support of the model. This calculation is done for each individual network used in the model.
value

A list of adjacency matrix of length nnets(object) or, if specified nnets(newdata).

Examples

data(fivenets)

# bernoulli graph
fit <- ergmito(fivenets ~ edges)

# all ties have the same likelihood
# which is roughly equal to:
# mean(nedges(fivenets)/(nvertex(fivenets)*(nvertex(fivenets) - 1)))
predict(fit)

# If we take into account vertex attributes, now the story is different!
fit <- ergmito(fivenets ~ edges + nodematch("female"))

# Not all ties have the same likelihood, since it depends on homophily!
predict(fit)

rbernoulli

Random Bernoulli graph

Description

Random Bernoulli graph

Usage

rbernoulli(n, p = 0.5)

Arguments

n

Integer vector. Size of the graph. If length(n) > 1, then it will a list of random graphs.

p

Probability of a tie. This may be either a scalar, or a vector of the same length of n.

Value

If n is a single number, a square matrix of size n with zeros in the diagonal. Otherwise it returns a list of length(n) square matrices of sizes equal to those specified in n.
same_dist

Examples

# A graph of size 4
rbernoulli(4)

# 3 graphs of various sizes
rbernoulli(c(3, 4, 2))

# 3 graphs of various sizes and different probabilities
rbernoulli(c(3, 4, 6), c(.1, .2, .3))

<table>
<thead>
<tr>
<th>same_dist</th>
<th>Compare pairs of networks to see if those came from the same distribution</th>
</tr>
</thead>
</table>

Description

If two networks are of the same size, and their vertex attributes are equal in terms of set comparison, then we say those came from the same distribution.

Usage

same_dist(net0, net1, ...)

## S3 method for class 'matrix'

same_dist(net0, net1, attrnames = NULL, ...)

## S3 method for class 'network'

same_dist(net0, net1, attrnames = NULL, ...)

Arguments

- net0, net1: Networks to be compared.
- ...: Ignored.
- attrnames: Character vector. (optional) Names of the vertex attributes to be be compared on. This is ignored in the matrix case.

Details

This function is used during the call of `ergmito_formulae` to check whether the function can recycle previously computed statistics for the likelihood function. In the case of models that only contain structural terms, i.e. attribute less, this can save significant amount of computing time and memory.

Value

A logical with an attribute `what`. TRUE meaning that the two networks come from the same distribution, and FALSE meaning that they do not. If FALSE the `what` attribute will be equal to either "size" or the name of the attribute that failed the comparison.
simulate.ergmito

Examples

```r
data(fivenets)
same_dist(fivenets[[1]], fivenets[[2]]) # Yes, same size
same_dist(fivenets[[1]], fivenets[[2]], "female") # No, different attr dist
```

```
simulate.ergmito

Draw samples from a fitted ergmito model

Description

Draw samples from a fitted ergmito model

Usage

```r
## S3 method for class 'ergmito'
simulate(object, nsim = 1, seed = NULL, which_networks = 1L, theta = NULL, ...)
```

Arguments

- **object** An object of class `ergmito`.
- **nsim** Integer scalar. Number of samples to draw from the selected set of networks.
- **seed** See `stats::simulate`
- **which_networks** Integer vector. Specifies what networks to sample from. It must be within 1 and `nnets(object)`.
- **theta, ...** Further arguments passed to `new_rergmito`.

Examples

```r
data(fivenets)
fit <- ergmito(fivenets ~ edges + nodematch("female"))

# Drawing 200 samples from networks 1 and 3 from the model
ans <- simulate(fit, nsim = 200, which_networks = c(1, 3))
```
