Package ‘ff’

October 13, 2020

Version  4.0.4
Date    2020-10-13
Title   Memory-Efficient Storage of Large Data on Disk and Fast Access
Functions

Author  Daniel Adler [aut],
        Christian Gläser [aut],
        Oleg Nenadic [aut],
        Jens Oehlschlägel [aut, cre],
        Martijn Schuemie [aut],
        Walter Zucchini [aut]

Maintainer Jens Oehlschlägel <Jens.Oehlschlaegel@truecluster.com>
Depends R (>= 2.10.1), bit (>= 4.0.0), utils
Suggests biglm, testthat (>= 0.11.0)

Description The ff package provides data structures that are stored on
disk but behave (almost) as if they were in RAM by transparently
mapping only a section (pagesize) in main memory - the effective
virtual memory consumption per ff object. ff supports R's standard
atomic data types 'double', 'logical', 'raw' and 'integer' and
non-standard atomic types boolean (1 bit), quad (2 bit unsigned),
nibble (4 bit unsigned), byte (1 byte signed with NAs), ubyte (1 byte
unsigned), short (2 byte signed with NAs), ushort (2 byte unsigned),
single (4 byte float with NAs). For example 'quad' allows efficient
storage of genomic data as an 'A','T','G','C' factor. The unsigned
types support 'circular' arithmetic. There is also support for
close-to-atomic types 'factor', 'ordered', 'POSIXct', 'Date' and
custom close-to-atomic types.
ff not only has native C-support for vectors, matrices and arrays
with flexible dimorder (major column-order, major row-order and
generalizations for arrays). There is also a fddf class not unlike
data.frames and import/export filters for csv files.
ff objects store raw data in binary flat files in native encoding,
and complement this with metadata stored in R as physical and virtual
attributes. ff objects have well-defined hybrid copying semantics,
which gives rise to certain performance improvements through
virtualization. `ff` objects can be stored and reopened across R
sessions. `ff` files can be shared by multiple `ff` R objects
(using different data en/de-coding schemes) in the same process
or from multiple R processes to exploit parallelism. A wide choice of
finalizer options allows to work with ’permanent’ files as well as
creating/removing ’temporary’ `ff` files completely transparent to the
user. On certain OS/Filesystem combinations, creating the `ff` files
works without notable delay thanks to using sparse file allocation.
Several access optimization techniques such as Hybrid Index
Preprocessing and Virtualization are implemented to achieve good
performance even with large datasets, for example virtual matrix
transpose without touching a single byte on disk. Further, to reduce
disk I/O, ”logicals” and non-standard data types get stored native and
compact on binary flat files i.e. logicals take up exactly 2 bits to
represent TRUE, FALSE and NA.
Beyond basic access functions, the `ff` package also provides
compatibility functions that facilitate writing code for `ff` and ram
objects and support for batch processing on `ff` objects (e.g. as.ram,
as.ff, ffapply). `ff` interfaces closely with functionality from package
’bit’: chunked looping, fast bit operations and coercions between
different objects that can store subscript information (’bit’,
’bitwhich’, ff ’boolean’, ri range index, hi hybrid index). This allows
to work interactively with selections of large datasets and quickly
modify selection criteria.
Further high-performance enhancements can be made available upon request.

add

Incrementing an ff or ram object

Description

Yet another assignment interface in order to allow to formulate \(x[index, \ldots, add=TRUE]<-value\) in a way which works transparently, not only for ff, but also for ram objects: add(x, value, index, \ldots).

Usage

```r
add(x, ...)  
## S3 method for class 'ff'
add(x, value, ...)  
## Default S3 method:
add(x, value, ...)
```

Arguments

- `x` an ff or ram object
- `value` the amount to increment, possibly recycled
- `...` further arguments – especially index information – passed to \([<-\) or \([<-.ff\)

Value

invisible()

Note

Note that add.default changes the object in its parent frame and thus violates R’s usual functional programming logic. Duplicated index positions should be avoided, because ff and ram objects behave differently:

```r
add.ff(x, 1, c(3,3))  
# will increment x at position 3 TWICE by 1, while
add.default(x, 1, c(3,3))  
# will increment x at position 3 just ONCE by 1
```

Examples

message("incrementing parts of a vector")
x <- ff(0, length=12)
y <- rep(0, 12)
add(x, 1, 1:6)
add(y, 1, 1:6)
x
y

message("incrementing parts of a matrix")
x <- ff(0, dim=3:4)
y <- array(0, dim=3:4)
add(x, 1, 1:2, 1:2)
add(y, 1, 1:2, 1:2)
x
y

message("BEWARE that ff and ram methods differ in treatment of duplicated index positions")
add(x, 1, c(3,3))
add(y, 1, c(3,3))
x
y

rm(x); gc()

array2vector                        Array: make vector from array

Description

Makes a vector from an array respecting 'dim' and 'dimorder'

Usage

array2vector(x, dim = NULL, dimorder = NULL)

Arguments

x               an array
dim             dim
dimorder        dimorder

Details

This is the inverse function of vector2array. It extracts the vector from the array by first moving through the fastest rotating dimension dim[dimorder[1]], then dim[dimorder[2]], and so forth
arrayIndex2vectorIndex

Value

a vector

Author(s)

Jens Oehlschlägel

See Also

vector2array, arrayIndex2vectorIndex

Examples

array2vector(matrix(1:12, 3, 4))
array2vector(matrix(1:12, 3, 4, byrow=TRUE), dimorder=2:1)

arrayIndex2vectorIndex

Array: make vector positions from array index

Description

Make vector positions from a (non-symmetric) array index respecting ‘dim’ and ‘dimorder’

Usage

arrayIndex2vectorIndex(x, dim = NULL, dimorder = NULL, vw = NULL)

Arguments

x an n by m matrix with n m-dimensional array indices
dim NULL or dim
dimorder NULL or dimorder
vw NULL or integer vector[3] or integer matrix[3,m], see details

Details

The fastest rotating dimension is dim[dimorder[1]], then dim[dimorder[2]], and so forth.
The parameters ’x’ and ’dim’ may refer to a subarray of a larger array, in this case, the array indices ’x’ are interpreted as ‘vw[1,] + x’ within the larger array ’as.integer(colSums(vw))’.

Value

a vector of indices in seq_len(prod(dim)) (or seq_len(prod(colSums(vw))))

Author(s)

Jens Oehlschlägel

array2vector, vectorIndex2arrayIndex

Examples

x <- matrix(1:12, 3, 4)
x
arrayIndex2vectorIndex(cbind(as.vector(row(x)), as.vector(col(x))),
dim=dim(x))
arrayIndex2vectorIndex(cbind(as.vector(row(x)), as.vector(col(x))),
dim=dim(x), dimorder=2:1)
matrix(1:30, 5, 6)
arrayIndex2vectorIndex(cbind(as.vector(row(x)), as.vector(col(x))),
vw=rbind(c(0,1), c(3,4), c(2,1)))
arrayIndex2vectorIndex(cbind(as.vector(row(x)), as.vector(col(x))),
vw=rbind(c(0,1), c(3,4), c(2,1)), dimorder=2:1)

---

as.ff  Coercing ram to ff and ff to ram objects

Description

Coercing ram to ff and ff to ram objects while optionally modifying object features.

Usage

as.ff(x, ...)
as.ram(x, ...)
## Default S3 method:
as.ff(x, filename = NULL, overwrite = FALSE, ...)
## S3 method for class 'ff'
as.ff(x, filename = NULL, overwrite = FALSE, ...)
## Default S3 method:
as.ram(x, ...)
## S3 method for class 'ff'
as.ram(x, ...)

Arguments

x any object to be coerced
filename path and filename
overwrite TRUE to overwrite the old filename
... ...
Details

If \texttt{as.ff} is called on an ‘ff’ object or \texttt{as.ram.default} is called on a non-ff object AND no changes are required, the input object ‘x’ is returned unchanged. Otherwise the workhorse \texttt{clone.ff} is called. If no change of features are requested, the filename attached to the object remains unchanged, otherwise a new filename is requested (or can be set by the user).

Value

A ram or ff object.

Note

If you use \texttt{ram <- as.ram(ff)} for caching, please note that you must \texttt{close.ff} before you can write back \texttt{as.ff(ram, overwrite=TRUE)} (see examples).

Author(s)

Jens Oehlschlägel

See Also

\texttt{as.ff.bit, ff, clone, as.vmode, vmode, as.hi}

Examples

\begin{verbatim}
message("create ff")
myintff <- ff(1:12)
message("coerce (=clone) integer ff to double ff")
mydoubleff <- as.ff(myintff, vmode="double")
message("cache (=clone) integer ff to integer ram AND close original ff")
myintram <- as.ram(myintff) # filename is retained
close(myintff)
message("modify ram cache and write back (=clone) to ff")
myintram[1] <- -1L
myintff <- as.ff(myintram, overwrite=TRUE)
message("coerce (=clone) integer ram to double ram")
mydoubleram <- as.ram(myintram, vmode="double")
message("coerce (inplace) integer ram to double ram")
myintram <- as.ram(myintram, vmode="double")
message("more classic: coerce (inplace) double ram to integer ram")
vmode(myintram) <- "integer"
rm(myintff, myintram, mydoubleff, mydoubleram); gc()
\end{verbatim}
### Description

Function `as.ff.bit` converts a `bit` vector to a boolean `ff` vector. Function `as.bit.ff` converts a boolean `ff` vector to a `ff` vector.

### Usage

```r
## S3 method for class 'bit'
as.ff(x, filename = NULL, overwrite = FALSE, ...)
## S3 method for class 'ff'
as.bit(x, ...)
```

### Arguments

- `x`: the source of conversion
- `filename`: optionally a desired filename
- `overwrite`: logical indicating whether we allow overwriting the target file
- `...`: further arguments passed to `ff` in case of `as.ff.bit`, ignored in case of `as.bit.ff`

### Details

The data are copied bit-wise but integer-wise, therefore these conversions are very fast. `as.bit.ff` will attach the `ff` filename to the `bit` vector, and `as.ff.bit` will - if attached - use this filename and SILENTLY overwrite this file.

### Value

A vector of the converted type

### Note

NAs are mapped to TRUE in `bit` and to FALSE in `ff` booleans. Might be aligned in a future release. Don’t use bit if you have NAs - or map NAs explicitly.

### Author(s)

Jens Oehlschlägel

### See Also

`bit.ff, as.ff, as.hi.bit`
Examples

```r
l <- as.boolean(sample(c(FALSE, TRUE), 1000, TRUE))

b <- as.bit(l)
stopifnot(identical(l, b[]))
b
f <- as.ff(b)
stopifnot(identical(l, f[]))
f
b2 <- as.bit(f)
stopifnot(identical(l, b2[]))
b2
f2 <- as.ff(b2)
stopifnot(identical(filename(f), filename(f2)))
stopifnot(identical(l, f2[]))
f
rm(f, f2); gc()
```

as.ffdf

**Coercing to ffdf and data.frame**

Description

Functions for coercing to ffdf and data.frame

Usage

```r
as.ffdf(x, ...)
## S3 method for class 'ff_vector'
as.ffdf(x, ...)
## S3 method for class 'ff_matrix'
as.ffdf(x, ...)
## S3 method for class 'data.frame'
as.ffdf(x, vmode=NULL, col_args = list(), ...)
## S3 method for class 'ffdf'
as.data.frame(x, ...)
```

Arguments

- **x**  
  the object to be coerced

- **vmode**  
  optional specification of the vmodes of columns of the data.frame. Either a character vector of vmodes (named with column names of the data.frame or recycled if not named) or a list named with vmodes where each element identifies those columns of the data.frame that should get the vmode encoded in the name of the element

- **col_args**  
  further arguments; passed to ff

- **...**  
  further arguments; passed to ffdf for .ff_vector, .ff_matrix and .data.frame methods, ignored for .ffdf identity method
Value

'as.ffdf' returns an object of class `ffdf', 'as.data.frame' returns an object of class `data.frame`

Author(s)

Jens Oehlschlägel

See Also

`is.ffdf, ffdf, data.frame`

Examples

```r
  d <- data.frame(x=1:26, y=letters, z=Sys.time()+1:26, stringsAsFactors = TRUE)
  ffd <- as.ffdf(d)
  stopifnot(identical(d, as.data.frame(ffd)))
  rm(ffd); gc()
```

Description

The generic `as.hi` and its methods are the main (internal) means for preprocessing index information into the hybrid index class `hi`. Usually `as.hi` is called transparently from `[.ff`. However, you can explicitly do the index-preprocessing, store the Hybrid Index `hi`, and use the `hi` for subscripting.

Usage

```r
  as.hi(x, ...) # S3 method for class 'NULL'
  as.hi(x, ...) # S3 method for class 'hi'
  as.hi(x, ...) # S3 method for class 'ri'
  as.hi(x, maxindex = length(x), ...) # S3 method for class 'bit'
  as.hi(x, range = NULL, maxindex = length(x), vw = NULL, dim = NULL, dimorder = NULL, pack = TRUE, ...) # S3 method for class 'bitwhich'
  as.hi(x, maxindex = length(x), pack = FALSE, ...) # S3 method for class 'call'
  as.hi(x, maxindex = NA, dim = NULL, dimorder = NULL, vw = NULL, vw.convert = TRUE, pack = TRUE, envir = parent.frame(), ...) # S3 method for class 'name'
  as.hi(x, envir = parent.frame(), ...)
```
## S3 method for class 'integer'

```r
as.hi(x, maxindex = NA, dim = NULL, dimorder = NULL,
     symmetric = FALSE, fixdiag = NULL, vw = NULL, vw.convert = TRUE,
     dimorder.convert = TRUE, pack = TRUE, NAs = NULL, ...)
```

## S3 method for class 'which'

```r
as.hi(x, ...)
```

## S3 method for class 'double'

```r
as.hi(x, ...)
```

## S3 method for class 'logical'

```r
as.hi(x, maxindex = NA, vw = NULL, pack = TRUE, ...)
```

## S3 method for class 'character'

```r
as.hi(x, names, vw = NULL, vw.convert = TRUE, ...)
```

## S3 method for class 'matrix'

```r
as.hi(x, dim, dimorder = NULL, symmetric = FALSE, fixdiag = NULL,
     vw = NULL, pack = TRUE, ...)
```

### Arguments

- **x**: an appropriate object of the class for which we dispatched
- **envir**: the environment in which to evaluate components of the index expression
- **maxindex**: maximum positive index position; `maxindex`, is needed with negative indices, if `vw` or `dim` is given, `maxindex` is calculated automatically
- **names**: the `names` of the indexed vector for character indexing
- **dim**: the `dim` of the indexed matrix to be stored within the `hi` object
- **dimorder**: the `dimorder` of the indexed matrix to be stored within the `hi` object, may convert interpretation of `x`
- **symmetric**: the `symmetric` of the indexed matrix to be stored within the `hi` object
- **fixdiag**: the `fixdiag` of the indexed matrix to be stored within the `hi` object
- **vw**: the virtual window `vw` of the indexed vector or matrix to be stored within the `hi` object, see details
- **vw.convert**: FALSE to prevent doubly virtual window conversion, this is needed for some internal calls that have done the virtual window conversion already, see details
- **dimorder.convert**: FALSE to prevent doubly dimorder conversion, this is needed for some internal calls that have done the dimorder conversion already, see details
- **NAs**: a vector of NA positions to be stored `rlepacked`, not fully supported yet
- **pack**: FALSE to prevent `rlepack`ing, note that this is a hint rather than a guarantee, `as.hi.bit` might ignore this
- **range**: NULL or a vector with two elements indicating first and last position to be converted from 'bit' to 'hi'
- **...**: further argument passed from generic to method or from wrapper method to `as.hi.integer`
Details

The generic dispatches appropriately, as.hi hi returns an hi object unchanged, as.hi.call tries to hiparse instead of evaluate its input in order to save RAM. If parsing is successful as.hi.call will ignore its argument pack and always pack unless the subscript is too small to do so. If parsing fails it evaluates the index expression and dispatches again to one of the other methods. as.hi.name and as.hi(.) are wrappers to as.hi.call. as.hi.integer is the workhorse for coercing evaluated expressions and as.hi.which is a wrapper removing the which class attribute. as.hi.double, as.hi.logical and as.hi.character are also wrappers to as.hi.integer, but note that as.hi.logical is not memory efficient because it expands all positions and then applies logical subcripting.

as.hi.matrix calls arrayIndex2vectorIndex and then as.hi.integer to interpret and preprocess matrix indices.

If the dim and dimorder parameter indicate a non-standard dimorder (dimorderStandard), the index information in x is converted from a standard dimorder interpretation to the requested dimorder. If the vw parameter is used, the index information in x is interpreted relative to the virtual window but stored relative to the absolute origin. Back-coercion via as.integer.hi and friends will again return the index information relative to the virtual window, thus retaining symmetry and transparency of the virtual window to the user.

You can use length to query the index length (possibly length of negative subscripts), poslength to query the number of selected elements (even with negative subscripts), and maxindex to query the largest possible index position (within virtual window, if present). Duplicated negative indices are removed and will not be recovered by as.integer.hi.

Value

an object of class hi

Note

Avoid changing the Hybrid Index representation, this might crash the [.ff subscripting.

Author(s)

Jens Oehlschlägel

See Also

hi for the Hybrid Index class, hiparse for parsing details, as.integer.hi for back-coercion, [.ff for ff subscripting

Examples

message("integer indexing with and without rel-packing")
as.hi(1:12)
as.hi(1:12, pack=FALSE)
message("if index is double, the wrapper method just converts to integer")
as.hi(as.double(1:12))
message("if index is character, the wrapper method just converts to integer")
as.hi(c("a","b","c"), names=letters)
message("negative index must use maxindex (or vw)")
as.integer.hi

Hybrid Index, coercing from

Description

Functions that (back-)convert an hi object to the respective subscripting information.

Usage

## S3 method for class 'hi'
as.which(x, ...)
## S3 method for class 'hi'
as.bitwhich(x, ...)
## S3 method for class 'hi'
as.integer(x, ...)  
## S3 method for class 'hi'
as.integer(x, vw.convert = TRUE, ...)
## S3 method for class 'hi'
as.logical(x, maxindex = NULL, ...)
## S3 method for class 'hi'
as.character(x, names, vw.convert = TRUE, ...)
## S3 method for class 'hi'
as.matrix(x, dim = x$dim, dimorder = x$dimorder, vw = x$vw, symmetric = x$symmetric, fixdiag = x$fixdiag, ...)

### Arguments

- **x**: an object of class `hi`
- **maxindex**: the length of the subscripted object (needed for logical output)
- **names**: the names vector of the subscripted object
- **dim**: the dim of the subscripted object
- **dimorder**: the dimorder of the subscripted object
- **vw**: the virtual window `vw` of the subscripted object
- **vw.convert**: `vw.convert`
- **symmetric**: TRUE if the subscripted matrix is symmetric
- **fixdiag**: TRUE if the subscripted matrix has fixdiag
- **...**: further arguments passed

### Value

`as.integer.hi` returns an integer vector, see `as.hi.integer`. `as.logical.hi` returns a logical vector, see `as.hi.logical`. `as.character.hi` returns a character vector, see `as.hi.character`. `as.matrix.hi` returns a matrix index, see `as.hi.matrix`.

### Author(s)

Jens Oehlschlägel

### See Also

- `hi`, `as.hi`

### Examples

```r
x <- 1:6
names(x) <- letters[1:6]
as.integer(as.hi(c(1:3)))
as.logical(as.hi(c(TRUE,TRUE,TRUE,FALSE,FALSE,FALSE)))
as.character(as.hi(letters[1:3], names=names(x)), names=names(x))
x <- matrix(1:12, 6)
as.matrix(as.hi(rbind(c(1,1), c(1,2), c(2,1)), dim=dim(x)), dim=dim(x))
```
as.vmode

Coercing to virtual mode

Description

as.vmode is a generic that converts some R ram object to the desired vmode.

Usage

as.vmode(x, ...)  
as.boolean(x, ...)  
as.quad(x, ...)  
as.nibble(x, ...)  
as.byte(x, ...)  
as.ubyte(x, ...)  
as.short(x, ...)  
as.ushort(x, ...)  
## Default S3 method:  
as.vmode(x, vmode, ...)  
## S3 method for class 'ff'  
as.vmode(x, ...)  
## Default S3 method:  
as.boolean(x, ...)  
## Default S3 method:  
as.quad(x, ...)  
## Default S3 method:  
as.nibble(x, ...)  
## Default S3 method:  
as.byte(x, ...)  
## Default S3 method:  
as.ubyte(x, ...)  
## Default S3 method:  
as.short(x, ...)  
## Default S3 method:  
as.ushort(x, ...)

Arguments

x any object
vmode virtual mode
... The ... don’t have a function yet, they are only defined to keep the generic flexible.

Details

Function as.vmode actually coerces to one of the usual storage.modes (see .rammode) but flags them with an additional attribute 'vmode' if necessary. The coercion generics can also be called
directly:

- `as.boolean` 1 bit logical without NA
- `as.logical` 2 bit logical with NA
- `as.quad` 2 bit unsigned integer without NA
- `as.nibble` 4 bit unsigned integer without NA
- `as.byte` 8 bit signed integer with NA
- `as.ubyte` 8 bit unsigned integer without NA
- `as.short` 16 bit signed integer with NA
- `as.ushort` 16 bit unsigned integer without NA
- `as.integer` 32 bit signed integer with NA
- `as.single` 32 bit float
- `as.double` 64 bit float
- `as.complex` 2x64 bit float
- `as.raw` 8 bit unsigned char
- `as.character` character

**Value**

A vector of the desired vmode containing the input data

**Author(s)**

Jens Oehlschlägel

**See Also**

`vmode`, `vector.vmode`

**Examples**

```r
as.vmode(1:3,"double")
as.vmode(1:3,"byte")
as.double(1:3)
as.byte(1:3)
```

**Description**

`bigsample` samples quicker from large pools than `sample` does.
Usage

```r
bigsample(x, ...)
## Default S3 method:
  bigsample(x, size, replace = FALSE, prob = NULL, negative = FALSE, ...)
## S3 method for class 'ff'
  bigsample(x, size, replace = FALSE, prob = NULL, ...)
```

Arguments

- `x` the pool to sample from
- `size` the number of elements to sample
- `replace` TRUE to use sampling with replacement
- `prob` optional vector of sampling probabilities (recycled to pool length)
- `negative` negative
- `...` ...

Details

For small pools `sample` is called.

Value

a vector of elements sampled from the pool (argument `x`)

Note

Note that `bigsample` and `sample` do not necessarily return the same sequence of elements when `set.seed` is set before.

Author(s)

Daniel Adler, Jens Oehlschlägel, Walter Zucchini

See Also

`sample`, `ff`

Examples

```r
message("Specify pool size")
bigsample(1e8, 10)
message("Sample ff elements (same as x[bigsample(length(ff(1:100 / 10)), 10)])")
bigsample(ff(1:100 / 10), 10)
## Not run:
message("Speed factor")
  (system.time(for(i in 1:10)sample(1e8, 10))[3]/10)
/ (system.time(for(i in 1:1000)bigsample(1e8, 10))[3]/1000)
## End(Not run)```
Collapsing functions for batch processing

Description

These are used in aggregating the chunks resulting from batch processing. They are usually called via do.call

Usage

ccbind(...)
crbind(...)
cfun(..., FUN, FUNARGS = list())
cquantile(..., probs = seq(0, 1, 0.25), na.rm = FALSE, names = TRUE, type = 7)
csummary(..., na.rm = "ignored")
cmedian(..., na.rm = FALSE)
clength(..., na.rm = FALSE)
csum(..., na.rm = FALSE)
cmean(..., na.rm = FALSE)

Arguments

... ... 
FUN a aggregating function
FUNARGS further arguments to the aggregating function
na.rm TRUE to remove NAs
probs see quantile
names see quantile
type see quantile

Details

<table>
<thead>
<tr>
<th>CFUN</th>
<th>FUN</th>
<th>comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>ccbind</td>
<td>cbind</td>
<td>like cbind but respecting names</td>
</tr>
<tr>

<td>length</td>
<td>crbind the input chunks and then determine the number of values in each column</td>
</tr>
<tr>
<td>csum</td>
<td>sum</td>
<td>crbind the input chunks and then determine the sum values in each column</td>
</tr>
<tr>
<td>cmean</td>
<td>mean</td>
<td>crbind the input chunks and then determine the (unweighted) mean in each column</td>
</tr>
</tbody>
</table>
In order to use CFUNs on the result of `lapply` or `ffapply` use `do.call`.

**Value**

depends on the CFUN used

**ff options**

xx TODO: extend this for weighted means, weighted median etc.,
google "Re: [R] Weighted median"

**Note**

Currently - for command line convenience - we map the elements of a single list argument to ...., but this may change in the future.

**Author(s)**

Jens Oehlschlägel

**See Also**

`ffapply`, `do.call`, `na.count`

**Examples**

```r
X <- lapply(split(rnorm(1000), 1:10), summary)
do.call("crbind", X)
do.call("csummary", X)
do.call("cmean", X)
do.call("cfun", c(X, list(FUN=mean, FUNARGS=list(na.rm=TRUE))))
rm(X)
```

---

**Description**

Chunking method for `ff_vector` and `ffdf` objects (row-wise) automatically considering RAM requirements from recordsize as calculated from `sum(.rambytes[vmode])`

**Usage**

```r
## S3 method for class 'ff_vector'
chunk(x
  , RECORDBYTES = .rambytes[vmode(x)], BATCHBYTES = getOption("ffbatchbytes"), ...)
## S3 method for class 'ffdf'
chunk(x
  , RECORDBYTES = sum(.rambytes[vmode(x)]), BATCHBYTES = getOption("ffbatchbytes"), ...)
```
Arguments

- **x**  
  ff or ffdf

- **RECORDBYTES**  
  optional integer scalar representing the bytes needed to process an element of the ff_vector a single row of the ffdf

- **BATCHBYTES**  
  integer scalar limiting the number of bytes to be processed in one chunk, default from `getOption("ffbatchbytes")`, see also .rambytes

- ...  
  further arguments passed to chunk

Value

- A list with ri indexes each representing one chunk

Author(s)

- Jens Oehlschlägel

See Also

- chunk, ffdf

Examples

x <- data.frame(x=as.double(1:26), y=factor(letters), z=ordered(LETTERS), stringsAsFactors = TRUE)
a <- as.ffdf(x)
ceiling(26 / (300 %/% sum(.rambytes[vmode(a)])))
chunk(a, BATCHBYTES=300)
ceiling(13 / (100 %/% sum(.rambytes[vmode(a)])))
chunk(a, from=1, to = 13, BATCHBYTES=100)
rm(a); gc()

message("dummy example for linear regression with biglm on ffdf")

    biglmfit <- biglm(form, data=firis[i,,drop=FALSE])
  }else{
    message("next chunk is: ", i[[1]],"," ,i[[2]])
    biglmfit <- update(bigmfit, firis[i,,drop=FALSE])
  }
}

summary(lmfit)
summary(biglmfit)
stopifnot(all.equal(coef(lmfit), coef(biglmfit)))

clone.f

Cloning ff and ram objects

Description

clone physically duplicates ff (and ram) objects and can additionally change some features, e.g. length.

Usage

```r
## S3 method for class 'ff'
clone(x
  , initdata = x
  , length = NULL
  , levels = NULL
  , ordered = NULL
  , dim = NULL
  , dimorder = NULL
  , bydim = NULL
  , symmetric = NULL
  , fixdiag = NULL
  , names = NULL
  , dimnames = NULL
  , ramclass = NULL
  , ramattrs = NULL
  , vmode = NULL
  , update = NULL
  , pattern = NULL
  , filename = NULL
  , overwrite = FALSE
  , pagesize = NULL
  , caching = NULL
  , finalizer = NULL
  , finonexit = NULL
  , FF_RETURN = NULL
  , BATCHSIZE = .Machine$integer.max
  , BATCHBYTES = getOption("ffbatchbytes")
  , VERBOSE = FALSE
  , ...)
```

Arguments

- `x`
clone.ff

initdata scalar or vector of the \texttt{vimplmented vmodes}, recycled if needed, default 0, see also \texttt{as.vmode} and \texttt{vector.vmode}

length optional vector \texttt{length} of the object (default: derive from \texttt{initdata} or \texttt{dim}), see \texttt{length.ff}

levels optional character vector of levels if (in this case initdata must be composed of these) (default: derive from initdata)

ordered indicate whether the levels are ordered (TRUE) or non-ordered factor (FALSE, default)

dim optional array \texttt{dim}, see \texttt{dim.ff} and \texttt{array}

dimorder physical layout (default seq\_along(dim)), see \texttt{dimorder} and \texttt{aperm}

bydim dimorder by which to interpret the \texttt{initdata}, generalization of the \texttt{byrow} parameter in \texttt{matrix}

symmetric extended feature: TRUE creates symmetric matrix (default FALSE)

fixdiag extended feature: non-NUL scalar requires fixed diagonal for symmetric matrix (default NULL is free diagonal)

names see \texttt{names}

dimnames NOT taken from initdata, see \texttt{dimnames}

ramclass class attribute attached when moving all or parts of this ff into ram, see \texttt{ramclass}

ramattrs additional attributes attached when moving all or parts of this ff into ram, see \texttt{ramattrs}

vmode virtual storage mode (default: derive from \texttt{initdata}), see \texttt{vmode} and \texttt{as.vmode}

update set to FALSE to avoid updating with \texttt{initdata} (default TRUE) (used by \texttt{ffdf})

pattern root pattern for automatic ff filename creation (default "ff"), see also \texttt{physical}

filename \texttt{ff} filename (default tmpfile with \texttt{pattern} prefix), see also \texttt{physical}

overwrite set to TRUE to allow overwriting existing files (default FALSE)

pagesize pagesize in bytes for the memory mapping (default from getOptions("fipagesize") initialized by \texttt{getdefaultpagesize}), see also \texttt{physical}

caching caching scheme for the backend, currently \texttt{mmnoflush} or \texttt{mmeachflush} (flush mmpages at each swap, default from getOptions("ffcaching") initialized with \texttt{memorymap}), see also \texttt{physical}

finalizer name of finalizer function called when ff object is removed, (default "deleteIfOpen" from getOptions("fffinalizer")), standard finalizers are \texttt{close.ff}, \texttt{delete.ff} and \texttt{deleteIfOpen.ff}, see also \texttt{reg.finalizer}

finonexit logical scalar determining whether finalizer is also called when R is closed via \texttt{q}, (default TRUE from getOptions("fffinonexit"))

FF\_RETURN logical scalar or ff object to be used. The default NULL creates a ff or ram clone, TRUE returns a ff clone, FALSE returns a ram clone. Handing over an ff object here uses this or stops if not \texttt{ffsuitable}

BATCHSIZE integer scalar limiting the number of elements to be processed in \texttt{update.ff} when length(initdata)>1, default from getOption("ffbatchsize")

BATCHBYTES integer scalar limiting the number of bytes to be processed in \texttt{update.ff} when length(initdata)>1, default from getOption("ffbatchbytes"), see also \texttt{.rambytes}

VERBOSE set to TRUE for verbosing in \texttt{update.ff} when length(initdata)>1, default FALSE

... further arguments to the generic
clone.ffdf

Details

close is generic. clone.ff is the workhorse behind as.ram and as.ff. For creating the desired object it calls ff which calls update for initialization.

Value

an ff or ram object

Author(s)

Jens Oehlschlägel

See Also

ff, update, as.ram, as.ff

Examples

x <- ff(letters, levels=letters)
y <- clone(x, length=52)
rm(x,y); gc()

clone.ffdf

Cloning ffdf objects

Description

close physically duplicates ffdf objects

Usage

## S3 method for class 'ffdf'
clone(x, nrow=FALSE, ...)

Arguments

x an ffdf

nrow optionally the desired number of rows in the new object. Currently this works only together with initdata=NULL

... further arguments passed to clone (usually not usefull)

Details

Creates a deep copy of an ffdf object by cloning all physical components including the row.names

Value

An object of type ffdf
Author(s)

Jens Oehlschlägel

See Also

close.ff

Examples

```r
x <- as.ffdf(data.frame(a=1:26, b=letters, stringsAsFactors = TRUE))

message("Here we change the content of both x and y by reference")
y <- x
x$a[1] <- -1
y$a[1]

message("Here we change the content only of x because y is a deep copy")
y <- clone(x)
x$a[2] <- -2
y$a[2]
rm(x, y); gc()
```

---

close.ff

Closing ff files

Description

Close frees the Memory Mapping resources and closes the ff file without deleting the file data.

Usage

```r
## S3 method for class 'ff'
close(con, ...)
## S3 method for class 'ffdf'
close(con, ...)
## S3 method for class 'ff_pointer'
close(con, ...)
```

Arguments

- `con` an open ff object
- `...` ...

Details

The `ff_pointer` method is not intended for manual use, it is used at finalizer dispatch time. Closing `ffdf` objects will close all of their physical components including their row.names if they are is.ff
Value

TRUE if the file could be closed, FALSE if it was closed already (or NA if not all components of an ffdf returned FALSE or TRUE on closing)

Author(s)

Jens Oehlschlägel

See Also

`ff`, `open.ff`, `delete`, `deleteIfOpen`

Examples

```r
x <- ff(1:12)
close(x)
x
open(x)
x
rm(x); gc()
```

---

**delete**  
Deleting the file behind an ff object

Description

The generic `delete` deletes the content of an object without removing the object itself. The generic `deleteIfOpen` does the same, but only if `is.open` returns TRUE.

Usage

```r
delete(x, ...)
deleteIfOpen(x, ...)
## S3 method for class 'ff'
delete(x, ...)
## S3 method for class 'ffdf'
delete(x, ...)
## S3 method for class 'ff_pointer'
delete(x, ...)
## Default S3 method:
delete(x, ...)
## S3 method for class 'ff'
deleteIfOpen(x, ...)
## S3 method for class 'ff_pointer'
deleteIfOpen(x, ...)
```
Arguments

- `x`: an ff or ram object
- `...`: further arguments (not used)

Details

The proper sequence to fully delete an ff object is: `delete(x);rm(x)`, where `delete.ff` frees the Memory Mapping resources and deletes the ff file, leaving intact the R-side object including its `class`, `physical` and `virtual` attributes. The default method is a compatibility function doing something similar with ram objects: by assigning an empty list to the name of the ram object to the parent frame we destroy the content of the object, leaving an empty stub that prevents raising an error if the parent frame calls the `delete(x);rm(x)` sequence. The `deleteIfOpen` does the same as `delete` but protects closed ff objects from deletion, it is mainly intended for use through a finalizer, as are the `ff_pointer` methods.

Value

`delete` returns TRUE if the/all ff files could be removed and FALSE otherwise. `deleteIfOpen` returns TRUE if the/all ff files could be removed, FALSE if not and NA if the ff object was open.

Note

Deletion of ff files can be trigged automatically via three routes:

1. if an ff object with a 'delete' finalizer is removed
2. if an ff object was created with `fffinonexit=TRUE` the finalizer is also called when R shuts down.
3. if an ff object was created in `getOption("fftempdir")`, it will be unlinked together with the `fftempdir.onUnload`

Thus in order to retain an ff file, one has to create it elsewhere than in `fftempdir` with a finalizer that does not destroy the file (by default files outside `fftempdir` get a 'close' finalizer) i.e. one of the following:

1. name the file AND use `fffinalizer="close"`
2. name the file AND use `fffinalizer="deleteIfOpen"` AND close the ff object before leaving R
3. name the file AND use `fffinalizer="delete"` AND use `fffinonexit=FALSE`

Author(s)

Jens Oehlschlägel

See Also

`ff, close.ff, open.ff, reg.finalizer`
Examples

message('create the ff file outside getOption("fftempir"),
    it will have default finalizer "close", so you need to delete it explicitly')
x <- ff(1:12, pattern="./ffexample")
delete(x)
rm(x)

dim.ff

Getting and setting dim and dimorder

Description

Assigning dim to an ff_vector changes it to an ff_array. Beyond that dimorder can be assigned to change from column-major order to row-major order or generalizations for higher order ff_array.

Usage

## S3 method for class 'ff'
dim(x)
## S3 method for class 'ffdf'
dim(x)
## S3 replacement method for class 'ff'
dim(x) <- value
## S3 replacement method for class 'ffdf'
dim(x) <- value
dimorder(x, ...) <- value
## Default S3 method:
dimorder(x, ...)
## S3 method for class 'ff_array'
dimorder(x, ...)
## S3 method for class 'ffdf'
dimorder(x, ...)
## S3 method for class 'ff_array'
dimorder(x, ...)
## S3 replacement method for class 'ff_array'
dimorder(x, ...) <- value
## S3 replacement method for class 'ffdf'
dimorder(x, ...) <- value # just here to catch forbidden assignments

Arguments

x a ff object
value an appropriate integer vector
... further arguments (not used)
Details

`dim` and `dimorder` are virtual attributes. Thus two copies of an R `ff` object can point to the same file but interpret it differently. `dim` has the usual meaning, `dimorder` defines the dimension order of storage, i.e. `c(1,2)` corresponds to R’s standard column-major order, `c(1,2)` corresponds to row-major order, and for higher dimensional arrays `dimorder` can also be used. Standard `dimorder` is `seq_along(dim(x))`.

For `ffdf` `dim` returns the number of rows and virtual columns. With `dim<-.ffdf` only the number of rows can be changed. For convenience you can assign `NA` to the number of columns.

For `ffdf` the `dimorder` returns non-standard `dimorder` if any of its columns contains a `ff` object with non-standard `dimorder` (see `dimorderStandard`) An even higher level of virtualization is available using virtual windows, see `vw`.

Value

`names` returns a character vector (or `NULL`)  

Note

`x[]` returns a matrix like `x[,]` and thus respects `dimorder`, while `x[i:j]` returns a vector and simply returns elements in the stored order. Check the corresponding example twice, in order to make sure you understand that for non-standard `dimorder` `x[seq_along(x)]` is not the same as `as.vector(x[])`.

Author(s)

Jens Oehlschlägel

See Also

`dim, dimnames.ff_array, dimorderStandard, vw, virtual`

Examples

```r
x <- ff(1:12, dim=c(3,4), dimorder=c(2:1))
y <- x
dim(y) <- c(4,3)
dimorder(y) <- c(1:2)
x
y
x[]
y[]
x[,bydim=c(2,1)]
y[,bydim=c(2,1)]

message("NOTE that x[] like x[,] returns a matrix (respects dimorder),")
message("while x[1:12] returns a vector IN STORAGE ORDER")
message("check the following examples twice to make sure you understand this")
x[,] x[]
as.vector(x[])```
## Not run:
message("some performance comparison between different dimorders")
n <- 100
m <- 100000
a <- ff(1L, dim=c(n,m))
b <- ff(1L, dim=c(n,m), dimorder=2:1)

system.time(lapply(1:n, function(i)sum(a[i,])))
system.time(lapply(1:n, function(i)sum(b[i,])))

system.time(lapply(1:n, function(i){i<-(i-1)*(m/n)+1; sum(a[,i:(i+m/n-1)])}))

system.time(lapply(1:n, function(i){i<-(i-1)*(m/n)+1; sum(b[,i:(i+m/n-1)])}))

rm(a,b); gc()

## End(Not run)

### dimnames.ff

**Getting and setting dimnames**

**Description**

For `ff_arrays` you can set dimnames.

**Usage**

```r
## S3 method for class 'ff_array'
dimnames(x)
## S3 replacement method for class 'ff_array'
dimnames(x) <- value
```

**Arguments**

- `x`: a `ff` array or matrix
- `value`: a list with length(`dim(x)`) elements (either NULL or character vector of length of dimension)

**Details**

If `vw` is set, `dimnames.ff_array` returns the appropriate part of the names, but you can’t set `dimnames` while `vw` is set. `dimnames` returns NULL for `ff_vectors` and setting `dimnames` for `ff_vector` is not allowed, but setting `names` is.

**Value**

`dimnames` returns a list, see `dimnames`
Author(s)
Jens Oehlschlägel

See Also
dimnames, dim.ff, names.ff, vw, virtual

Examples

```r
x <- ff(1:12, dim=c(3,4), dimnames=list(letters[1:3], LETTERS[1:4]))
dimnames(x)
dimnames(x) <- list(LETTERS[1:3], letters[1:4])
dimnames(x)
dimnames(x) <- NULL
dimnames(x)
rm(x); gc()
```

Description
Getting and setting dimnames of ffdf

Usage

```r
## S3 method for class 'ffdf'
dimnames(x)

## S3 replacement method for class 'ffdf'
dimnames(x) <- value

## S3 method for class 'ffdf'
names(x)

## S3 replacement method for class 'ffdf'
names(x) <- value

## S3 method for class 'ffdf'
row.names(x)

## S3 replacement method for class 'ffdf'
row.names(x) <- value
```

Arguments

- `x`: a ffdf object
- `value`: a character vector, or, for dimnames a list with two character vectors

Details
It is recommended not to assign row.names to a large ffdf object.
Value
The assignment function return the changed ffdf object. The other functions return the expected.

Author(s)
Jens Oehlschlägel

See Also
ffdf, dimnames.ff, rownames, colnames

Examples
ffd <- as.ffdf(data.frame(a=1:26, b=letters, stringsAsFactors = TRUE))
dimnames(ffd)
row.names(ffd) <- letters
dimnames(ffd)
ffd
rm(ffd); gc()

Description
dimorderStandard returns TRUE if the dimorder is standard (ascending), vectorStandard returns TRUE if the dimorder-bydim combination is compatible with a standard elementwise vector interpretation, dimorderCompatible returns TRUE if two dimorders have a compatible elementwise vector interpretation and vectorCompatible returns TRUE if dimorder-bydim combinations have a compatible elementwise vector interpretation.

Usage
dimorderStandard(dimorder)
vectorStandard(dimorder, bydim = NULL)
dimorderCompatible(dim, dim2, dimorder, dimorder2)
vectorCompatible(dim, dim2, dimorder=NULL, dimorder2=NULL, bydim = NULL, bydim2 = NULL)

Arguments
dim a dim
dim2 a dim
dimorder a dimorder
dimorder2 a dimorder
bydim a bydim order, see [.ff
bydim2 a bydim order, see argument fromdim in update.ff
**Value**

TRUE if compatibility has been detected, FALSE otherwise

**Note**

does not yet guarantee to detect all compatible configurations, but the most important ones

Jens Oehlschlägel

**See Also**

dimorder, ffconform

---

dummy.dimnames  
Array: make dimnames

**Description**

makes standard dimnames from letters and integers (for testing)

**Usage**

dummy.dimnames(x)

**Arguments**

x  
an array

**Value**

a list with character vectors suitable to be assigned as dimnames to x

**Author(s)**

Jens Oehlschlägel

**See Also**

dimnames

**Examples**

dummy.dimnames(matrix(1:12, 3, 4))
Description

These are the main methods for reading and writing data from ff files.

Usage

```r
## S3 method for class 'ff'
x[i, pack = FALSE]
## S3 replacement method for class 'ff'
x[i, add = FALSE, pack = FALSE] <- value
## S3 method for class 'ff_array'
x[... , bydim = NULL, drop =getOption("ffdrop"), pack = FALSE]
## S3 replacement method for class 'ff_array'
x[... , bydim = NULL, add = FALSE, pack = FALSE] <- value
## S3 method for class 'ff'
x[[i]]
## S3 replacement method for class 'ff'
x[[i, add = FALSE]] <- value
```

Arguments

- `x` an ff object
- `i` missing OR a single index expression OR a hi object
- `...` missing OR up to length(dim(x)) index expressions OR hi objects
- `drop` logical scalar indicating whether array dimensions shall be dropped
- `bydim` the dimorder which shall be used in interpreting vector to/from array data
- `pack` FALSE to prevent rle-packing in hybrid index preprocessing, see `as.hi`
- `value` the values to be assigned, possibly recycled
- `add` TRUE if the values should rather increment than overwrite at the target positions, see `readwrite.ff`

Details

The single square bracket operators `[` and `[<-` are the workhorses for accessing the content of an ff object. They support `ff_vector` and `ff_array` access (dim.ff), they respect virtual windows (vw), names.ff and dimnames.ff and retain ramclass and ramattrs and thus support POSIXct and factor, see levels.ff.

The functionality of `[` and `[<-` can be combined into one efficient operation, see `swap`.

The double square bracket operator `[[` is a shortcut for `get.ff` resp. `set.ff`, however, you should not rely on this for the future, see `LimWarn`. For programming please prefer `[`. 

---

**Reading and writing vectors and arrays (high-level)**

---
### Value

The read operators `[` and `[[` return data from the ff object, possibly decorated with `names`, `dim`, `dimnames` and further attributes and classes (see `ramclass`, `ramattrs`).

The write operators `<-` and `[[<-` return the ‘modified’ ff object (like all assignment operators do).

### Index expressions

```r
x <- ff(1:12, dim=c(3,4), dimnames=list(letters[1:3],NULL))
```

### Dimorder and bydim

Arrays in R have always standard `dimorder` `seq_along(dim(x))` while ff allows to store an array in a different dimorder. Using nonstandard dimorder (see `dimorderStandard`) can speed up certain access operations: while matrix `dimorder=c(1,2)` – column-major order – allows fast extraction of columns, `dimorder=c(2,1)` allows fast extraction of rows.

While the dimorder – being an attribute of an `ff_array` – controls how the vector in an ff file is interpreted, the `bydim` argument to the extractor functions controls, how assignment vector values in `[<-` are translated to the array and how the array is translated to a vector in `[` subscripting. Note that `bydim=c(2,1)` corresponds to `matrix(...,byrow=TRUE)`.

### Multiple vector interpretation in arrays

In case of non-standard dimorder (see `dimorderStandard`) the vector sequence of array elements in R and in the ff file differs. To access array elements in file order, you can use `getset.ff`, `readwrite.ff` or copy the ff object and set `dim(ff)<-NULL` to get a vector view into the ff object (using `[` dispatches the vector method `.[.ff]`). To access the array elements in R standard dimorder you simply use `[` which dispatches to `.[.ff_array]`. Note that in this case `as.hi` will unpack the complete index, see next section.

### RAM expansion of index expressions

Some index expressions do not consume RAM due to the `hi` representation, for example `1:n` will almost consume no RAM hoewever large n. However, some index expressions are expanded and require to `maxindex(i) * .rambytes["integer"]` bytes, either because the sorted sequence of index positions cannot be rle-packed efficiently or because `hiparse` cannot yet parse such expression and falls back to evaluating/expanding the index expression. If the index positions are not sorted,
the index will be expanded and a second vector is needed to store the information for re-ordering, thus the index requires $2 \times \text{maxindex}(i) \times \text{.rambytes["integer"]}$ bytes.

**RAM expansion when recycling assignment values**

Some assignment expressions do not consume RAM for recycling, for example $x[1:n] \leftarrow 1:k$ will not consume RAM however large $n$ compared to $k$, when $x$ has standard dimorder. However, if $\text{length(value)}>1$, assignment expressions with non-ascending index positions trigger recycling the value R-side to the full index length. This will happen if dimorder does not match parameter bydim or if the index is not sorted ascending.

## Extract.ffdf

### Reading and writing data.frames (ffdf)

#### Description

These are the main methods for reading and writing data from ffdf objects.

#### Usage

```r
## S3 method for class 'ffdf'
x[i, j, drop = ncols == 1]
## S3 replacement method for class 'ffdf'
x[i, j] <- value
## S3 method for class 'ffdf'
x[[i, j, exact = TRUE]]
## S3 replacement method for class 'ffdf'
x[[i, j]] <- value
```
## S3 method for class 'ffdf'

```r
x$i
```

## S3 replacement method for class 'ffdf'

```r
x$i <- value
```

### Arguments

- **x**: an ff object
- **i**: a row subscript or a matrix subscript or a list subscript
- **j**: a column subscript
- **drop**: logical. If TRUE the result is coerced to the lowest possible dimension. The default is to drop if only one column is left, but not to drop if only one row is left.
- **value**: A suitable replacement value: it will be repeated a whole number of times if necessary and it may be coerced: see the Coercion section. If NULL, deletes the column if a single column is selected with `[[<-` or `$<-`.
- **exact**: logical: see `.`, and applies to column names.

### Details

The subscript methods `[]`, `[[` and `$`, behave symmetrical to the assignment functions `<-`, `[[<-` and `$<-`. What the former return is the assignment value to the latter. A notable exception is assigning NULL in `[[<-` and `$<-` which removes the virtual column from the ffdf (and the physical component if it is no longer needed by any virtual column). Creating new columns via `[[<-` and `$<-` requires giving a name to the new column (character subscripting). `<-` does not allow to create new columns, only to replace existing ones.

#### Subscript expressions and return values

<table>
<thead>
<tr>
<th>allowed expression</th>
<th>example</th>
<th>returnvalue</th>
</tr>
</thead>
<tbody>
<tr>
<td>row selection</td>
<td><code>x[i,]</code></td>
<td>data.frame or single row as list if <code>drop=TRUE</code>, like from data.frame</td>
</tr>
<tr>

**ff**

*ff classes for representing (large) atomic data*

Description

The **ff** package provides atomic data structures that are stored on disk but behave (almost) as if they were in RAM by mapping only a section (pagesize) into main memory (the effective main memory consumption per **ff** object). Several access optimization techniques such as Hybrid Index Preprocessing (**as.hi, update.ff**) and Virtualization (**virtual, vt, vw**) are implemented to achieve good performance even with large datasets. In addition to the basic access functions, the **ff** package also provides compatibility functions that facilitate writing code for **ff** and ram objects (**clone, as.ff, as.ram**) and very basic support for operating on **ff** objects (**ffapply**). While the (possibly packed) raw data is stored on a flat file, meta informations about the atomic data structure such as its dimension, virtual storage mode (**vmode**), factor level encoding, internal length etc. are stored as an ordinary R object (external pointer plus attributes) and can be saved in the workspace. The raw flat file data encoding is always in native machine format for optimal performance and provides
several packing schemes for different data types such as logical, raw, integer and double (in an extended version support for more tightly packed virtual data types is supported). Flatfile data files can be shared among ff objects in the same R process or even from different R processes due to Memory-Mapping, although the caching effects have not been tested extensively. Please do read and understand the limitations and warnings in LimWarn before you do anything serious with package ff.

Usage

```r
ff( initdata = NULL,
    length = NULL,
    levels = NULL,
    ordered = NULL,
    dim = NULL,
    dimorder = NULL,
    bydim = NULL,
    symmetric = FALSE,
    fixdiag = NULL,
    names = NULL,
    dimnames = NULL,
    ramclass = NULL,
    ramattrs = NULL,
    vmode = NULL,
    update = NULL,
    pattern = NULL,
    filename = NULL,
    overwrite = FALSE,
    readonly = FALSE,
    pagesize = NULL # getOption("ffpagesize")
    caching = NULL # getOption("ffcaching")
    finalizer = NULL
    FF_RETURN = TRUE
    BATCHSIZE = .Machine$integer.max
    BATCHBYTES = getOption("ffbatchbytes")
    VERBOSE = FALSE
  )
```

Arguments

- `initdata`: scalar or vector of the `.vimplemented vmode`, recycled if needed, default 0, see also `as.vmode` and `vector.vmode`
- `length`: optional vector `length` of the object (default: derive from `initdata` or `dim`), see `length.ff`
- `levels`: optional character vector of levels if (in this case `initdata` must be composed of these) (default: derive from `initdata`)
- `ordered`: indicate whether the levels are ordered (TRUE) or non-ordered factor (FALSE, default)
optional array `dim`, see `dim.ff` and `array`

physical layout (default `seq_along(dim)`), see `dimorder` and `aperm`

dimorder by which to interpret the `initdata`, generalization of the `byrow` parameter

in `matrix`

TRUE creates symmetric matrix (default FALSE)

extended feature: non-NULL scalar requires fixed diagonal for symmetric matrix (default NULL is free diagonal)

NOT taken from `initdata`, see `names`

NOT taken from `initdata`, see `dimnames`

class attribute attached when moving all or parts of this `ff` into ram, see `ramclass`

additional attributes attached when moving all or parts of this `ff` into ram, see `ramattrs`

virtual storage mode (default: derive from `initdata`), see `vmode` and `as.vmode`

set to FALSE to avoid updating with `initdata` (default TRUE) (used by `ffdf`)

root pattern with or without path for automatic `ff` filename creation (default NULL translates to "ff"), see also argument ‘filename’

`ff` filename with or without path (default `tmpfile` with ‘pattern’ prefix); without path the file is created in `getOption("fftempdir")`, with path ‘.’ the file is created in `getwd`. Note that files created in `getOption("fftempdir")` have default finalizer “delete” while other files have default finalizer “close”. See also arguments ‘pattern’ and ‘finalizer’ and `physical`

set to TRUE to allow overwriting existing files (default FALSE)

set to TRUE to forbid writing to existing files

pagesize in bytes for the memory mapping (default from `getOption("ffpagesize")` initialized by `getdefaultpagesize`), see also `physical`

caching scheme for the backend, currently ‘mmnoflush’ or ‘mmeachflush’ (flush mmpages at each swap, default from `getOption("ffcaching")` initialized with ‘mmeachflush’), see also `physical`

name of finalizer function called when `ff` object is removed (default: `ff` files created in `getOptions("fftempdir")` are considered temporary and have default finalizer `delete`, files created in other locations have default finalizer `close`); available finalizer generics are "close", "delete" and "deleteIfOpen", available methods are `close.ff`, `delete.ff` and `deleteIfOpen.ff`, see also argument ‘finonexit’ and `finalizer`

logical scalar determining whether and `finalize` is also called when R is closed via `q`, (default TRUE from `getOption("fffinonexit")`)

logical scalar or `ff` object to be used. The default TRUE creates a new `ff` file. FALSE returns a ram object. Handing over an `ff` object here uses this or stops if not `ffsuitable`

integer scalar limiting the number of elements to be processed in `update.ff` when `length(initdata)>1`, default from `.Machine$integer.max`

integer scalar limiting the number of bytes to be processed in `update.ff` when `length(initdata)>1`, default from `getOption("ffbatchbytes")`, see also `rambytes`

set to TRUE for verbosing in `update.ff` when `length(initdata)>1`, default FALSE
Details

The atomic data is stored in `filename` as a native encoded raw flat file on disk, OS specific limitations of the file system apply. The number of elements per `ff` object is limited to the integer indexing, i.e., `.Machine$integer.max`. Atomic objects created with `ff` are `is.open`, a C++ object is ready to access the file via memory-mapping. Currently the C++ backend provides two caching schemes: `mnmonoflush` let the OS decide when to flush memory mapped pages and `mmeachflush` will flush memory mapped pages at each page swap per `ff` file. These minimal memory resources can be released by `close`ing or `delete`ing the `ff` file. `ff` objects can be `saved` and `loaded` across R sessions. If the `ff` file still exists in the same location, it will be `opened` automatically at the first attempt to access its data. If the `ff` object is `removed`, at the next garbage collection (see `gc`) the `ff` object’s `finalizer` is invoked. Raw data files can be made accessible as an `ff` object by explicitly given the filename and vmode but no size information (length or dim). The `ff` object will open the file and handle the data with respect to the given vmode. The `close` finalizer will close the `ff` file, the `delete` finalizer will delete the `ff` file. The default finalizer `deleteIfOpen` will delete open files and do nothing for closed files. If the default finalizer is used, two actions are needed to protect the `ff` file against deletion: create the file outside the standard ‘fftempdir’ and close the `ff` object before removing it or before quitting R. When R is exited through `q`, the finalizer will be invoked depending on the ‘fffinonexit’ option, furthermore the ‘fftempdir’ is `unlinked`.

Value

If (!$FF_RETURN) then a ram object like those generated by `vector`, `matrix`, `array` but with attributes ‘vmode’, ‘physical’ and ‘virtual’ accessible via `vmode`, `physical` and `virtual`

If ($FF_RETURN) an object of class ‘ff’ which is a list with two components:

- `physical` an external pointer of class ‘ff_pointer’ which carries attributes with copy by reference semantics: changing a physical attribute of a copy changes the original
- `virtual` an empty list which carries attributes with copy by value semantics: changing a virtual attribute of a copy does not change the original

Physical object component

The ‘ff_pointer’ carries the following ‘physical’ or readonly attributes, which are accessible via `physical`:

- `vmode` see `vmode`
- `maxlength` see `maxlength`
- `pattern` see parameter ‘pattern’
- `filename` see `filename`
- `pagesize` see parameter ‘pagesize’
- `caching` see parameter ‘caching’
- `finalizer` see parameter ‘finalizer’
- `finonexit` see parameter ‘finonexit’
- `readonly` see `is.readonly`
- `class` The external pointer needs class ‘ff\_pointer’ to allow method dispatch of finalizers
Virtual object component

The 'virtual' component carries the following attributes (some of which might be NULL):

- Length: see `length.ff`
- Levels: see `levels.ff`
- Names: see `names.ff`
- VW: see `vw.ff`
- Dim: see `dim.ff`
- Dimorder: see `dimorder`
- Symmetric: see `symmetric.ff`
- Fixdiag: see `fixdiag.ff`
- ramclass: see `ramclass`
- ramattribs: see `ramattribs`

Class

You should not rely on the internal structure of ff objects or their ram versions. Instead use the accessor functions like `vmode`, `physical` and `virtual`. Still it would be wise to avoid attributes AND classes 'vmode', 'physical' and 'virtual' in any other packages. Note that the 'ff' object's class attribute also has copy-by-value semantics ('virtual'). For the 'ff' object the following class attributes are known:

- vector: c("ff_vector","ff")
- matrix: c("ff_matrix","ff_array","ff")
- array: c("ff_array","ff")
- symmetric matrix: c("ff_symm","ff")
- distance matrix: c("ff_dist","ff_symm","ff")
- reserved for future use: c("ff_mixed","ff")

Methods

The following methods and functions are available for ff objects:

<table>
<thead>
<tr>
<th>Type</th>
<th>Name</th>
<th>Assign</th>
<th>Comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>function</td>
<td>ff</td>
<td></td>
<td>constructor for ff and ram objects</td>
</tr>
<tr>
<td>generic</td>
<td>update</td>
<td></td>
<td>updates one ff object with the content of another</td>
</tr>
<tr>
<td>generic</td>
<td>clone</td>
<td></td>
<td>clones an ff object optionally changing some of its features</td>
</tr>
<tr>
<td>method</td>
<td>print</td>
<td></td>
<td>print ff</td>
</tr>
<tr>
<td>method</td>
<td>str</td>
<td></td>
<td>ff object structure</td>
</tr>
</tbody>
</table>

**Basic functions**

**Class test and coercion**

| function | is.ff    |        | check if inherits from ff                   |
| generic  | as.ff    |        | coerce to ff, if not yet                    |
| generic  | as.ram   |        | coerce to ram retaining some of the ff information |
| generic  | as.bit   |        | coerce to bit                               |

**Virtual storage mode**

generic | vmode   | <-     | get and set virtual mode (setting only for ram, not for ff objects) |
generic  as.vmode  coerce to vmode (only for ram, not for ff objects)

**Physical attributes**

function  physical <-  set and get physical attributes
generic  filename <-  get and set filename
generic  pattern <-  get pattern and set filename path and prefix via pattern
generic  maxlength <-  get maxlength
generic  is.sorted <-  set and get if is marked as sorted
generic  na.count <-  set and get NA count, if set to non-NA only swap methods can change and na.count is maintained

generic  is.readonly <-  get if is readonly

**Virtual attributes**

function  virtual <-  set and get virtual attributes
method  length <-  set and get length
method  dim <-  set and get dim
generic  dimorder <-  set and get the order of dimension interpretation
generic  vt  virtually transpose ff_array
method  t  create transposed clone of ff_array
generic  vw <-  set and get virtual windows
method  names <-  set and get names
method  dimnames <-  set and get dimnames
generic  symmetric <-  get if is symmetric
generic  fixdiag <-  set and get fixed diagonal of symmetric matrix
method  levels <-  levels of factor
generic  recodeLevels  recode a factor to different levels
generic  sortLevels  sort the levels and recode a factor
method  is.factor  if is factor
method  is.ordered  if is ordered (factor)
generic  ramclass <-  get ramclass
generic  ramattribs <-  get ramattribs

**Access functions**

function  get.ff  get single ff element (currently [ ] is a shortcut)
function  set.ff  set single ff element (currently [ ]<- is a shortcut)
function  getset.ff  set single ff element and get old value in one access operation
function  read.ff  get vector of contiguous elements
function  write.ff  set vector of contiguous elements
function  readwrite.ff  set vector of contiguous elements and get old values in one access operation
method  [  get vector of indexed elements, uses HIP, see hi
method  [<-  set vector of indexed elements, uses HIP, see hi
generic  swap  set vector of indexed elements and get old values in one access operation
(generic  add  (almost) unifies ‘+=’ operation for ff and ram objects
generic  bigsample  sample from ff object

**Opening/Closing/Deleting**

check if ff is open
open ff object (is done automatically on access)
close ff object (releases C++ memory and protects against file deletion if deleteIfOpen)
deletes ff file (unconditionally)
deletes ff file if ff object is open (finalization method)
get and set finalizer
force finalization
### Other

- function `geterror.ff` — get error code
- function `geterrstr.ff` — get error message

### ff options

Through `options` or `getOption` one can change and query global features of the ff package:

<table>
<thead>
<tr>
<th>option</th>
<th>description</th>
<th>default</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>fftempdir</code></td>
<td>default directory for creating ff files</td>
<td><code>tempdir</code></td>
</tr>
<tr>
<td><code>fffinalizer</code></td>
<td>name of default finalizer</td>
<td><code>deleteIfOpen</code></td>
</tr>
<tr>
<td><code>fffinonexit</code></td>
<td>default for invoking finalizer on exit of R</td>
<td><code>TRUE</code></td>
</tr>
<tr>
<td><code>ffpagesize</code></td>
<td>default pagesize</td>
<td><code>getdefaultpagesize</code></td>
</tr>
<tr>
<td><code>ffcaching</code></td>
<td>caching scheme for the C++ backend</td>
<td><code>'mmnoflush'</code></td>
</tr>
<tr>
<td><code>ffdrop</code></td>
<td>default for the 'drop' parameter in the ff subscript methods</td>
<td><code>TRUE</code></td>
</tr>
<tr>
<td><code>ffbatchbytes</code></td>
<td>default for the byte limit in batched/chunked processing</td>
<td><code>memory.limit() %/% 100</code></td>
</tr>
</tbody>
</table>

### OS specific

<table>
<thead>
<tr>
<th>File System</th>
<th>File size limit</th>

**Description**

The `ffapply` functions support convenient batched processing of ff objects such that each single batch or chunk will not exhaust RAM and such that batches have sizes as similar as possible, see `bbatch`. Differing from R’s standard `apply` which applies a `FUNction`, the `ffapply` functions do apply an `EXPRession` and provide two indices `FROM="i1"` and `TO="i2"`, which mark beginning and end of the batch and can be used in the applied expression. Note that the `ffapply` functions change the two indices in their parent frame, to avoid conflicts you can use different names through `FROM="i1"` and `TO="i2"`. For support of creating return values see details.

**Usage**

```r
ffvecapply(EXPR, X = NULL, N = NULL, VMODE = NULL, VBYTES = NULL, RETURN = FALSE, CFUN = NULL, USE.NAMES = TRUE, FF_RETURN = TRUE, BREAK = ".break", FROM = "i1", TO = "i2", BATCHSIZE = .Machine$integer.max, BATCHBYTES = getOption("ffbatchbytes"), VERBOSE = FALSE)
```

```r
ffrowapply(EXPR, X = NULL, N = NULL, NCOL = NULL, VMODE = NULL, VBYTES = NULL, RETURN = FALSE, RETCOL = NCOL, CFUN = NULL, USE.NAMES = TRUE, FF_RETURN = TRUE, FROM = "i1", TO = "i2", BATCHSIZE = .Machine$integer.max, BATCHBYTES = getOption("ffbatchbytes"), VERBOSE = FALSE)
```

```r
ffcolapply(EXPR, X = NULL, N = NULL, NROW = NULL, VMODE = NULL, VBYTES = NULL, RETURN = FALSE, RETROW = NROW, CFUN = NULL, USE.NAMES = TRUE, FF_RETURN = TRUE, FROM = "i1", TO = "i2", BATCHSIZE = .Machine$integer.max, BATCHBYTES = getOption("ffbatchbytes"), VERBOSE = FALSE)
```

```r
ffapply(EXPR = NULL, AFUN = NULL, MARGIN = NULL, X = NULL, N = NULL, DIM = NULL, VMODE = NULL, VBYTES = NULL, RETURN = FALSE, CFUN = NULL, USE.NAMES = TRUE, IDIM = "idim", FF_RETURN = TRUE, BREAK = ".break", FROM = "i1", TO = "i2", BATCHSIZE = .Machine$integer.max, BATCHBYTES = getOption("ffbatchbytes"), VERBOSE = FALSE)
```

**Arguments**

- `EXPR` the **expression** to be applied
- `AFUN` `ffapply` only: alternatively to `EXPR` the name of a function to be applied, automatically converted to `EXPR`
- `MARGIN` `ffapply` only: the margins along which to loop in `ffapply`
- `X` an ff object from which several parameters can be derived, if they are not given directly: `N,NCOL,NROW,DIM,VMODE,VBYTES,FF_RETURN`
- `N` the total number of elements in the loop, e.g. number of elements in `ffvecapply` or number of rows in `ffrowapply`
- `NCOL` `ffrowapply` only: the number of columns needed to calculate batch sizes
- `NROW` `ffcolapply` only: the number of rows needed to calculate batch sizes
- `DIM` `ffapply` only: the dimension of the array needed to calculate batch sizes
ffapply

VMODE
the vmode needed to prepare the RETURN object and to derive VBYTES if they are not given directly

VBYTES
the bytes per cell – see .rambytes – to calculate the RAM requirements per cell

BATCHBYTES
the max number of bytes per batch, default getOption("ffbatchbytes")

BATCHSIZE
an additional restriction on the number of loop elements, default=.Machine$integer.max

FROM
the name of the index that marks the beginning of the batch, default 'i1', change if needed to avoid naming-conflicts in the calling frame

TO
the name of the index that marks the end of the batch, default 'i2', change if needed to avoid naming-conflicts in the calling frame

IDIM
ffapply only: the name of an R variable used for loop-switching, change if needed to avoid naming-conflicts in the calling frame

BREAK
ffapply only: the name of an R object in the calling frame that triggers break out of the batch loop, if 1) it exists 2) is.logical and 3) is TRUE

RETURN
TRUE to prepare a return value (default FALSE)

CFUN
name of a collapsing function, see CFUN

RETCOL
NULL gives return vector[1:N], RETCOL gives return matrix[1:N,1:RETCOL]

RETROW
NULL gives return vector[1:N], RETROW gives return matrix[1:RETROW,1:N]

FF_RETURN
FALSE to return a ram object, TRUE to return an ff object, or an ff object that is ffsuitable to absorb the return data

USE NAMES
FALSE to suppress attaching names or dimnames to the result

VERBOSE
TRUE to verbose the batches

Details

ffvecapply is the simplest ffapply method for ff_vectors. ffrowapply and ffcolapply is for ff_matrix, and ffapply is the most general method for ff_arrays and ffVectors.

There are many ways to change the return value of the ffapply functions. In its simplest usage – batched looping over an expression – they don’t return anything, see invisible. If you switch RETURN=TRUE in ffvecapply then it is assumed that all looped expressions together return one vector of length N, and via parameter FF_RETURN, you can decide whether this vector is in ram or is an ff object (or even which ff object to use). ffrowapply and ffcolapply additionally have parameter RETCOL resp. RETROW which defaults to returning a matrix of the original size: in order to just return a vector of length N set this to NULL, or specify a number of columns/rows for the return matrix. It is assumed that the expression will return appropriate pieces for this return structure (see examples). If you specify RETURN=TRUE and a collapsing function name CFUN, then it is assumed that the batched expressions return aggregated information, which is first collected in a list, and finally the collapsing function is called on this list: do.call(CFUN,list). If you want to return the unmodified list, you have to specify CFUN="list" for obvious reasons.

ffapply allows usages not completly unlike apply: you can specify the name of a function AFUN to be applied over MARGIN. However note that you must specify RETURN=TRUE in order to get a return value. Also note that currently ffapply assumes that your expression returns exactly one value per cell in DIM[MARGINS]. If you want to return something more complicated, you MUST specify a CFUN="list" and your return value will be a list with dim attribute DIM[MARGINS]. This means that for a function AFUN returning a scalar, ffapply behaves very similar to apply, see examples.
Note also that `ffapply` might create a object named `.ffapply.dimexhausted` in its parent frame, and it uses a variable in the parent frame for loop-switching between dimensions, the default name 'idim' can be changed using the IDIM parameter. Finally you can break out of the implied loops by assigning TRUE to a variable with the name in BREAK.

Value

see details

Note

xx The complete generation of the return value is preliminary and the arguments related to defining the return value might still change, especially `ffapply` is work in progress

ffconform

Get most conforming argument

Description
ffconform returns position of 'most' conformable ff argument or zero if the arguments are not conforming

Usage
ffconform(..., vmode = NULL, fail = "stop")

Arguments
...
two or more ff objects
vmode
handing over target vmode here supresses searching for a common vmode, see maxffmode
fail
the name of a function to call if not-conforming, default stop
Details

A reference argument is defined to be the first argument with a `dim` attribute or the longest vector. The other arguments are then compared to the reference to check for conformity, which is violated if v modes are not conforming or if the reference has not a multiple length of each other or if the dimensions do not match or if we have a dimorder conflict because not all arguments have the same `dimorderStandard`.

Value

the position of the most conforming argument or 0 (zero) if not conforming.

Note

xx Work in progress for package `R.ff`

Examples

```r
a <- ff(1:10)
b <- clone(a)
c <- ff(1:20)
d <- ff(1:21)
ffconform(a, b)
ffconform(c, a)
ffconform(a, c)
ffconform(c, a, b)
d1 <- ff(1:20, dim=c(2, 10))
d2 <- ff(1:20, dim=c(10, 2))
ffconform(c, d1)
ffconform(c, d2)
ffconform(d1, c)
ffconform(d2, c)
try(ffconform(d1, d2))
ffconform(d1, d1)

rm(a, b, c, d1, d2); gc()
```
ffdf

**ff class for data.frames**

**Description**

Function ‘ffdf’ creates ff data.frames stored on disk very similar to ‘data.frame’

**Usage**

```r
ffdf(...,
   row.names = NULL,
   ff_split = NULL,
   ff_join = NULL,
   ff_args = NULL,
   update = TRUE,
   BATCHSIZE = .Machine$integer.max,
   BATCHBYTES = getOption("ffbatchbytes"),
   VERBOSE = FALSE)
```

**Arguments**

- `...` ff vectors or matrices (optionally wrapped in `I()` that shall be bound together to an ffdf object
- `row.names` A character vector. Not recommended for large objects with many rows.
- `ff_split` A vector of character names or integer positions identifying input components to physically split into single ff_vectors. If vector elements have names, these are used as root name for the new ff files.
- `ff_join` A list of vectors with character names or integer positions identifying input components to physically join in the same ff matrix. If list elements have names, these are used to name the new ff files.
- `update` By default (TRUE) new ff files are updated with content of input ff objects. Setting to FALSE prevents this update.
- `ff_args` a list with further arguments passed to `ff` in case that new ff objects are created via ‘ff_split’ or ‘ff_join’
- `BATCHSIZE` passed to `update.ff`
- `BATCHBYTES` passed to `update.ff`
- `VERBOSE` passed to `update.ff`

**Details**

By default, creating an ‘ffdf’ object will NOT create new ff files, instead existing files are referenced. This differs from `data.frame`, which always creates copies of the input objects, most notably in `data.frame(matrix())`, where an input matrix is converted to single columns. `ffdf` by contrast, will store an input matrix physically as the same matrix and virtually map it to columns. Physically copying a large ff matrix to single ff vectors can be expensive. More generally, `ffdf`
objects have a **physical** and a **virtual** component, which allows very flexible dataframe designs: a physically stored matrix can be virtually mapped to single columns, a couple of physically stored vectors can be virtually mapped to a single matrix. The means to configure these are I for the virtual representation and the ‘ff_split’ and ‘ff_join’ arguments for the physical representation. An ff matrix wrapped into ‘I()’ will return the input matrix as a single object, using ‘ff_split’ will store this matrix as single vectors - and thus create new ff files. ‘ff_join’ will copy a couple of input vectors into a unified new ff matrix with dimorder=c(2,1), but virtually they will remain single columns. The returned ffdf object has also a **dimorder** attribute, which indicates whether the ffdf object contains a matrix with non-standard dimorder c(2,1), see **dimorderStandard**. Currently, **virtual windows** are not supported for ffdf.

**Value**

A list with components

- **physical** the underlying ff vectors and matrices, to be accessed via **physical**
- **virtual** the virtual features of the ffdf including the virtual-to-physical mapping, to be accessed via **virtual**
- **row.names** the optional row.names, see argument row.names

and class ’ffdf’ (NOTE that ffdf dows not inherit from ff)

**Methods**

The following methods and functions are available for ffdf objects:

</tbody>
</table>
method pattern <- set pattern (rename/move files)

**Access functions**

method [<- set and get data.frame content ([,]) or get ffdf with less columns ([])
method [<- set and get single column ff object
method $ <- set and get single column ff object

**Opening/Closing/Deleting**

generic is.open tri-bool is.open status of the physical ff components
method open open all physical ff objects (is done automatically on access)
method close close all physical ff objects
method delete deletes all physical ff files
method finalize call finalizer

**processing**

method chunk create chunked index
method sortLevels sort and recode levels

**Other**

**Note**

Note that in theory, accessing a chunk of rows from a matrix with
\(\text{dimorder}=c(2,1)\) should be faster than accessing across a bunch of vectors. However, at least under windows, the OS has difficulties filecaching parts from very large files, therefore - until we have partitioning - the recommended physical storage is in single vectors.

**Examples**

```r
m <- matrix(1:12, 3, 4, dimnames=list(c("r1","r2","r3"), c("m1","m2","m3","m4")))
v <- 1:3
ffm <- as.ff(m)
ffv <- as.ff(v)

d <- data.frame(m, v)
ffd <- ffdf(ffm, v=ffv, row.names=row.names(ffm))
all.equal(d, ffd[,])
ffd
physical(ffd)

d <- data.frame(m, v)
ffd <- ffdf(ffm, v=ffv, row.names=row.names(ffm), ff_split=1)
all.equal(d, ffd[,])
ffd
physical(ffd)
```
```r
d <- data.frame(m, v)
ffd <- ffdf(ffm, v=ffv, row.names=row.names(ffm), ff_join=list(newff=c(1,2)))
all.equal(d, ffd[,])
ffd
physical(ffd)

d <- data.frame(I(m), I(v))
ffd <- ffdf(m=I(ffm), v=I(ffv), row.names=row.names(ffm))
all.equal(d, ffd[,])
ffd
physical(ffd)
rm(ffm,ffv,ffd); gc()
```

---

**ffdfindexget**

Reading and writing ffdf data.frame using ff subscripts

### Description

Function `ffdfindexget` allows to extract rows from an ffdf data.frame according to positive integer subscripts stored in an ff vector. Function `ffdfindexset` allows the inverse operation: assigning to rows of an ffdf data.frame according to positive integer subscripts stored in an ff vector. These functions allow more control than the method dispatch of `[` and `[[<` if an ff integer subscript is used.

### Usage

```r
ffdfindexget(x, index, indexorder = NULL, autoindexorder = 3, FF_RETURN = NULL, BATCHSIZE = NULL, BATCHBYTES = getOption("ffmaxbytes"), VERBOSE = FALSE)
ffdfindexset(x, index, value, indexorder = NULL, autoindexorder = 3, FF_RETURN = NULL, BATCHSIZE = NULL, BATCHBYTES = getOption("ffmaxbytes"), VERBOSE = FALSE)
```

### Arguments

- **x**: A `ffdf` data.frame containing the elements
- **index**: A `ff` integer vector with integer subscripts in the range from 1 to `length(x)`.
- **value**: A `ffdf` data.frame like `x` with the rows to be assigned
- **indexorder**: Optionally the return value of `ffindexorder`, see details
- **autoindexorder**: The minimum number of columns (which need chunked indexordering) for which we switch from on-the-fly ordering to stored `ffindexorder`
- **FF_RETURN**: Optionally an `ffdf` data.frame of the same type as `x` in which the returned values shall be stored, see details.
- **BATCHSIZE**: Optimal limit for the batchsize (see details)
- **BATCHBYTES**: Limit for the number of bytes per batch
- **VERBOSE**: Logical scalar for verbosing
Details

Accessing rows of an ffdf data.frame identified by integer positions in an ff vector is a non-trivial task, because it could easily lead to random-access to disk files. We avoid random access by loading batches of the subscript values into RAM, order them ascending, and only then access the ff values on disk. Such ordering is done on-thy-fly for up to autoindexorder-1 columns that need ordering. For autoindexorder 0 more columns we do the batched ordering upfront with \texttt{ffindexorder} and then re-use it in each call to \texttt{ffindexget} resp. \texttt{ffindexset}.

Value

Function \texttt{ffdfindexget} returns a ffdf data.frame with those rows selected by the ff index vector. Function \texttt{ffdfindexset} returns \texttt{x} with those rows replaced that had been requested by \texttt{index} and \texttt{value}.

Examples

```r
message("ff integer subscripts with ffdf return/assign values")
x <- ff(factor(letters))
y <- ff(1:26)
d <- ffdf(x,y)
i <- ff(2:9)
di <- d[i,]
di
d[i,] <- di
message("ff integer subscripts: more control with ffindexget/ffindexset")
di <- ffdfindexget(d, i, FF_RETURN=di)
d <- ffdfindexset(d, i, di)
rm(x, y, d, i, di)
gc()
```

Description

These functions allow convenient sorting and ordering of collections of (ff) vectors organized in (ffdf) data.frames
Usage

\texttt{dforder(x, ...)}
\texttt{dfsor(x, ...)}
\texttt{ramdforder(x, ...)}
\texttt{ramdfsor(x, ...)}
\texttt{ffdforder(x, ...)}
\texttt{ffdfsor(x, ...)}

Arguments

\texttt{x} \hspace{1cm} \text{a data.frame (for dforder, dfsort, ramorder, ramsort) or an ffdf object (for ffdforder, ffdfsor)}

\texttt{...} \hspace{1cm} \text{further arguments passed to sort, ramsort or ffsort (for objects with one column) or passed to order, ramorder or fforder (for objects with multiple columns)}

Value

the order functions return an (ff) vector of integer order positions, the sort functions return a sorted clone of the (ffdf) input data.frame

ffindexget

Reading and writing ff vectors using ff subscripts

Description
Function ffindexget allows to extract elements from an ff vector according to positive integer suscripts stored in an ff vector.
Function ffindexset allows the inverse operation: assigning to elements of an ff vector according to positive integer suscripts stored in an ff vector. These functions allow more control than the method dispatch of [ and [<- if an ff integer subscript is used.
### Usage

```r
ffindexget(x, index, indexorder = NULL, FF_RETURN = NULL
, BATCHSIZE = NULL, BATCHBYTES = getOption("ffmaxbytes"), VERBOSE = FALSE)
ffindexset(x, index, value, indexorder = NULL
, BATCHSIZE = NULL, BATCHBYTES = getOption("ffmaxbytes"), VERBOSE = FALSE)
```

### Arguments

- **x**: A `ff` vector containing the elements
- **index**: A `ff` integer vector with integer subscripts in the range from 1 to `length(x)`.
- **value**: An `ff` vector of the same `vmode` as `x` containing the values to be assigned
- **indexorder**: Optionally the return value of `ffindexorder`, see details
- **FF_RETURN**: Optionally an `ff` vector of the same `vmode` as `x` in which the returned values shall be stored, see details.
- **BATCHSIZE**: Optional limit for the batchsize (see details)
- **BATCHBYTES**: Limit for the number of bytes per batch
- **VERBOSE**: Logical scalar for verbosing

### Details

Accessing integer positions in an `ff` vector is a non-trivial task, because it could easily lead to random-access to a disk file. We avoid random access by loading batches of the subscript values into RAM, order them ascending, and only then access the `ff` values on disk. Since ordering is expensive, it may pay to do the batched ordering once upfront and then re-use it with `ffindexorder`, similar to storing and using hybrid index information with `as.hi`.

### Value

Function `ffindexget` returns an `ff` vector with the extracted elements.
Function `ffindexset` returns the `ff` vector in which we have updated values.

### Author(s)

Jens Oehlschlägel

### See Also

`Extract.ff`, `ffdfindexget`, `ffindexorder`

### Examples

```r
message("ff integer subscripts with ff return/assign values")
x <- ff(factor(letters))
i <- ff(2:9)
xi <- x[i]

xi
xi[] <- NA
xi
```
```r
x[i] <- xi
x
message("ff integer subscripts: more control with ffindexget/ffindexset")
xi <- ffindexget(x, i, FF_RETURN=xi)
x <- ffindexset(x, i, xi)
rm(x, i, xi)
gc()
```

### ffindexorder

| Sorting: chunked ordering of integer subscript positions |

#### Description

Function `ffindexorder` will calculate chunkwise the order positions to sort all positions in a chunk ascending.

Function `ffindexordersize` does the calculation of the chunksize for `ffindexorder`.

#### Usage

```r
ffindexordersize(length, vmode, BATCHBYTES = getOption("ffmaxbytes"))
ffindexorder(index, BATCHSIZE, FF_RETURN = NULL, VERBOSE = FALSE)
```

#### Arguments

- **index**: A `ff` integer vector with integer subscripts.
- **BATCHSIZE**: Limit for the chunksize (see details)
- **BATCHBYTES**: Limit for the number of bytes per batch
- **FF_RETURN**: Optionally an `ff` integer vector in which the chunkwise order positions are stored.
- **VERBOSE**: Logical scalar for activating verbosing.
- **length**: Number of elements in the index
- **vmode**: The vmode of the `ff` vector to which the index shall be applied with `ffindexget` or `ffindexset`

#### Details

Accessing integer positions in an `ff` vector is a non-trivial task, because it could easily lead to random-access to a disk file. We avoid random access by loading batches of the subscript values into RAM, order them ascending, and only then access the `ff` values on disk. Such an ordering can be done on-the-fly by `ffindexget` or it can be created upfront with `ffindexorder`, stored and re-used, similar to storing and using hybrid index information with `as.hi`.

#### Value

Function `ffindexorder` returns an `ff` integer vector with an attribute `BATCHSIZE` (the chunksize finally used, not the one given with argument `BATCHSIZE`).

Function `ffindexordersize` returns a balanced batchsize as returned from `bbatch`.

rm(x,i,s,o)
gc()

ffinfo

Inspect content of ff saves

Description

Find out which objects and ff files are in a pair of files saved with ffsave

Usage

ffinfo(file)

Arguments

file a character string giving the name (without extension) of the .RData and .ffData files to load
Value

- **RData**: a list, one element for each object (named like the object): a character vector with the names of the ff files
- **ffData**: a list, one element for each path (names like the path): a character vector with the names of the ff files
- **rootpath**: the root path relative to which the files are stored in the .ffData zip

Note

For large files and the zip64 format use zip 3.0 and unzip 6.0 from [http://infozip.sourceforge.net/](http://infozip.sourceforge.net/).

Author(s)

Jens Oehlschlägel

See Also

- `ffsave`, `ffload`, `ffdrop`

---

**ffload**

Reload ffSaved Datasets

Description

Reload datasets written with the function `ffsave` or `ffsave.image`.

Usage

```r
ffload(file, list = character(0L), envir = parent.frame()
, rootpath = NULL, overwrite = FALSE)
```

Arguments

- **file**: a character string giving the name (without extension) of the .RData and .ffData files to load
- **list**: An optional vector of names selecting those objects to be restored (default NULL restores all)
- **envir**: the environment where the data should be loaded.
- **rootpath**: an optional rootpath where to restore the ff files (default NULL restores in the original location)
- **overwrite**: logical indicating whether possibly existing ff files shall be overwritten
fforder

Details

`ffinfo` can be used to inspect the contents an `ffsave` pair of `.RData` and `.ffData` files. Argument list can then be used to restore only part of the `ffsave`.

Value

A character vector with the names of the restored `ff` files

Note

The `ff` files are not platform-independent with regard to byte order. For large files and the zip64 format use `zip 3.0` and `unzip 6.0` from `http://infozip.sourceforge.net/`.

<table>
<thead>
<tr>
<th>fforder</th>
<th>Sorting: order from ff vectors</th>
</tr>
</thead>
</table>

Description

Returns order with regard to one or more `ff` vectors

Usage

```r
fforder(...
  , index = NULL
  , use.index = NULL
  , aux = NULL
  , auxindex = NULL
  , has.na = TRUE
  , na.last = TRUE
  , decreasing = FALSE
  , BATCHBYTES = getOption("ffmaxbytes")
  , VERBOSE = FALSE
)
```
Arguments

... one of more ff vectors which define the order
index an optional ff integer vector used to store the order output
use.index A boolean flag telling fforder whether to use the positions in 'index' as input. If you do this, it is your responsibility to assure legal positions - otherwise you risk a crash.
aux An optional named list of ff vectors that can be used for temporary copying – the names of the list identify the vnodes for which the respective ff vector is suitable.
auxindex An optional ff integer vector for temporary storage of integer positions.
has.na boolean scalar telling fforder whether the vector might contain NAs. Note that you risk a crash if there are unexpected NAs with has.na=FALSE
na.last boolean scalar telling fforder whether to order NAs last or first. Note that 'boolean' means that there is no third option NA as in order
decreasing boolean scalar telling fforder whether to order increasing or decreasing
BATCHBYTES maximum number of RAM bytes fforder should try not to exceed
VERBOSE cat some info about the ordering

Details

fforder tries to order the vector in-RAM, if not possible it uses (a yet simple) out-of-memory algorithm. Like ramorder the in-RAM ordering method is choosen depending on context information.

Value

An ff vector with the positions that ore required to sort the input as specified – with an attribute na.count with as many values as columns in ...

**ffreturn**  
*Return suitable ff object*

**Description**

*ffreturn* returns `FF_RETURN` if it is `ffsuitable` otherwise creates a suitable `ffsuitable` object.

**Usage**

```r
ffreturn(FF_RETURN = NULL, FF_PROTO = NULL, FF_ATTR = NULL)
```

**Arguments**

- **FF_RETURN** the object to be tested for suitability
- **FF_PROTO** the prototype object which `FF_RETURN` should match
- **FF_ATTR** a list of additional attributes dominating those from `FF_PROTO`

**Value**

a suitable `ffsuitable` object

**Note**

xx Work in progress for package *R.ff*

**Author(s)**

Jens Oehlschlägel

**See Also**

`ffconform, fsuitable`
Description

`ffsave` writes an external representation of R and ff objects to an `ffarchive`. The objects can be read back from the file at a later date by using the function `ffload`.

Usage

```r
ffsave(...
  , list = character(0L)
  , file = stop("'file' must be specified")
  , envir = parent.frame()
  , rootpath = NULL
  , add = FALSE

  , move = FALSE
  , compress = !move
  , compression_level = 6
  , precheck=TRUE
)
```

```r
ffsave.image(file = stop("'file' must be specified"), safe = TRUE, ...)
```

Arguments

- `...`: For `ffsave` the names of the objects to be saved (as symbols or character strings), for `ffsave.image` further arguments passed to `ffsave`
- `list`: A character vector containing the names of objects to be saved.
- `file`: A name for the `ffarchive`, i.e. the two files `<file>.RData` and `<file>.ffData`
- `envir`: environment to search for objects to be saved.
- `add`: logical indicating whether the objects shall be added to the `ffarchive` (in this case `rootpath` is taken from an existing archive)
- `move`: logical indicating whether ff files shall be moved instead of copied into the `<file>.ffData`
- `compress`: logical specifying whether saving to a named file is to use compression.
- `compression_level`: compression level passed to `zip`, default 6
- `rootpath`: optional path component that all all ff files share and that can be dropped/replaced when calling `ffload`
- `precheck`: logical: should the existence of the objects be checked before starting to save (and in particular before opening the file/connection)?
- `safe`: logical. If `TRUE`, a temporary file is used for creating the saved workspace. The temporary file is renamed to `<file>.ffData` if the save succeeds. This preserves an existing workspace `<file>.ffData` if the save fails, but at the cost of using extra disk space during the save.
Details

`ffsave` stores objects and ff files in an `ffarchive` named `<file>`: i.e. it saves all specified objects via `save` in a file named `<file>.RData` and saves all ff files related to these objects in a zipfile named `<file>.ffData` using an external zip utility.

By default files are stored relative to the `rootpath=""` and will be restored relative to `\code{""` (in its original location). By providing a partial path prefix via argument `rootpath` the files are stored relative to this rootpath. The rootpath is stored in the `<file>.RData` with the name `.ff.rootpath`. I.e. even if the ff objects were saved with argument `rootpath` to `ffsave`, `ffload` by default restores in the original location. By using argument `rootpath` to `ffload` you can restore relative to a different rootpath (and using argument `rootpath` to `ffsave` gave you shorter relative paths).

By using argument `add` in `ffsave` you can add more objects to an existing `ffarchive` and by using argument `list` in `ffload` you can selectively restore objects.

The content of the `ffarchive` can be inspected using `ffinfo` before actually loading any of the objects.

The `ffarchive` can be deleted from disk using `ffdrop`.

Value

A character vector with messages returned from the zip utility (one for each ff file zipped)

Note

The ff files are not platform-independent with regard to byte order. For large files and the zip64 format use `zip 3.0` and unzip 6.0 from `http://infozip.sourceforge.net/`.

Author(s)

Jens Oehlschlägel

See Also

`ffinfo` for inspecting the content of the `ffarchive`
`ffload` for loading all or some of the `ffarchive`
`ffdrop` for deleting one or more `ffarchives`

Examples

```r
# Not run:
message("let's create some ff objects")
n <- 8e3
a <- ff(sample(n, n, TRUE), vmode="integer", length=n, filename="d:/tmp/a.ff")
b <- ff(sample(255, n, TRUE), vmode="ubyte", length=n, filename="d:/tmp/b.ff")
x <- ff(sample(255, n, TRUE), vmode="ubyte", length=n, filename="d:/tmp/x.ff")
y <- ff(sample(255, n, TRUE), vmode="ubyte", length=n, filename="d:/tmp/y.ff")
z <- ff(sample(255, n, TRUE), vmode="ubyte", length=n, filename="d:/tmp/z.ff")
df <- ffdf(x=x, y=y, z=z)
rm(x,y,z)
message("save all of them")
```
ffsave.image("d:/tmp/x")
str(ffinfo("d:/tmp/x"))

message("save some of them with shorter relative pathnames ...")
ffsave(a, b, file="d:/tmp/y", rootpath="d:/tmp")
str(ffinfo("d:/tmp/y"))

message("... and add others later")
ffsave(df, add=TRUE, file="d:/tmp/y", rootpath="d:/tmp")
str(ffinfo("d:/tmp/y"))

message("... and add others later")
system.time(ffsave(a, file="d:/tmp/z", move=TRUE))
ffinfo("d:/tmp/z")

message("let's delete/close/remove all objects")
close(a) # no file anymore, since we moved a into the ffarchive
delete(b, df)
rm(df, a, b, n)
message("prove it")
ls()

message("restore all but ff files in a different directory")
system.time(ffload("d:/tmp/x", rootpath="d:/tmp2"))
lapply(ls(), function(i)filename(get(i)))

delete(a, b, df)
rm(df, a, b)

ffdrop(c("d:/tmp/x", "d:/tmp/y", "d:/tmp/z"))

## End(Not run)

ffsort

Sorting of ff vectors

Description

Sorting: sort an ff vector – optionally in-place

Usage

ffsort(x
  , aux = NULL
  , has.na = TRUE
  , na.last = TRUE
  , decreasing = FALSE
  , inplace = FALSE
  , decorate = FALSE
  , BATCHBYTES = getOption("ffmaxbytes")

Arguments

x an ff vector
aux NULL or an ff vector of the same type for temporary storage
has.na boolean scalar telling ffsort whether the vector might contain NAs. Note that you risk a crash if there are unexpected NAs with has.na=FALSE
na.last boolean scalar telling ffsort whether to sort NAs last or first. Note that 'boolean’ means that there is no third option NA as in sort
decreasing boolean scalar telling ffsort whether to sort increasing or decreasing
inplace boolean scalar telling ffsort whether to sort the original ff vector (TRUE) or to create a sorted copy (FALSE, the default)
decorate boolean scalar telling ffsort whether to decorate the returned ff vector with is.sorted and na.count attributes.
BATCHBYTES maximum number of RAM bytes ffsort should try not to exceed
VERBOSE cat some info about the sorting

Details

ffsort tries to sort the vector in-RAM respecting the BATCHBYTES limit. If a fast sort it not possible, it uses a slower in-place sort (shellsort). If in-RAM is not possible, it uses (a yet simple) out-of-memory algorithm. Like ramsort the in-RAM sorting method is choosen depending on context information. If a key-index sort can be used, ffsort completely avoids merging disk based subsorts. If argument decorate=TRUE is used, then na.count(x) will return the number of NAs and is.sorted(x) will return TRUE if the sort was done with na.last=TRUE and decreasing=FALSE.

Value
An ff vector – optionally decorated with is.sorted and na.count, see argument ‘decorate’

Note
the ff vector may not have a names attribute

Author(s)
Jens Oehlschlägel

See Also
ramsort, fforder, ffdfsort
**Examples**

```r
n <- 1e6
x <- ff(c(NA, 999999:1), vmode="double", length=n)
x <- ffsort(x)
x
is.sorted(x)
na.count(x)
x <- ffsort(x, decorate=TRUE)
is.sorted(x)
na.count(x)
x <- ffsort(x, BATCHBYTES=n, VERBOSE=TRUE)
```

---

**ffsuitable**

*Test ff object for suitability*

**Description**

`ffsuitable` tests whether `FF_RETURN` is an `ff` object like `FF_PROTO` and having attributes `FF_ATTR`.

**Usage**

```r
ffsuitable(FF_RETURN, FF_PROTO = NULL, FF_ATTR = list(),
          strict.dimorder = TRUE, fail = "warning")
```

**Arguments**

- `x`: an object from which to extract attributes for comparison
- `FF_RETURN`: the object to be tested for suitability
- `FF_PROTO`: the prototype object which `FF_RETURN` should match
- `FF_ATTR`: a list of additional attributes dominating those from `FF_PROTO`
- `strict.dimorder`: if TRUE `ffsuitability` requires that the dimorders are standard (ascending)
- `fail`: name of a function to be called if not `ffsuitable` (default `warning`)

**Value**

`TRUE` if `FF_RETURN` object is suitable, `FALSE` otherwise

**Note**

- `xx` Work in progress for package `R.ff`

**Author(s)**

ffxtensions

See Also

ffconform, ffreturn

Description

checks if this version of package ff supports ff extensions.

Usage

ffxtensions()
ffsymmxtensions()

Details

ff extensions are needed for certain bitcompressed vmodes and ff symm extensions for symmetric matrices.

Value

logical scalar

Author(s)

Jens Oehlschlägel

See Also

vmode

Examples

ffxtensions()
ffsymmxtensions()
file.resize

Change size of move an existing file

Description

Change size of an existing file (on some platforms sparse files are used) or move file to other name and/or location.

Usage

file.resize(path, size)
file.move(from, to)

Arguments

path file path (on windows it uses a 'windows' backslash path!)
size new filesize in bytes as double
from old file path
to new file path

Details

file.resize can enlarge or shrink the file. When enlarged, the file is filled up with zeros. Some platform implementations feature sparse files, so that this operation is very fast. We have tested:

- Ubuntu Linux 8, i386
- FreeBSD 7, i386
- Gentoo Linux Virtual-Server, i386
- Gentoo Linux, x86_64
- Windows XP

The following work but do not support sparse files

- Mac OS X 10.5, i386
- Mac OS X 10.4, PPC

file.move tries to file.rename, if this fails (e.g. across file systems) the file is copied to the new location and the old file is removed, see file.copy and file.remove.

Value

logical scalar representing the success of this operation

Author(s)

Daniel Adler
filename

See Also

file.create, file.rename, file.info, file.copy, file.remove

Examples

x <- tempfile()
newsize <- 23 # resize and size to 23 bytes.
file.resize(x, newsize)
file.info(x)$size == newsize
## Not run:
newsize <- 8*(2^30) # create new file and size to 8 GB.
file.resize(x, newsize)
file.info(x)$size == newsize

## End(Not run)
y <- tempfile()
file.move(x,y)
file.remove(y)

filename

Get or set filename

Description

Get or set filename from ram or ff object via the filename and filename<- generics or rename all files behind a ffdf using the pattern<- generic.

Usage

filename(x, ...)
filename(x, ...) <- value
## Default S3 method:
filename(x, ...)
## S3 method for class 'ff_pointer'
filename(x, ...)
## S3 method for class 'ffdf'
filename(x, ...)
## S3 replacement method for class 'ff'
filename(x, ...) <- value
pattern(x, ...)
pattern(x, ...) <- value
## S3 method for class 'ff'
pattern(x, ...)
## S3 replacement method for class 'ff'
pattern(x, ...) <- value
## S3 replacement method for class 'ffdf'
pattern(x, ...) <- value
Arguments

x  a ram or ff object, or for pattern assignment only - a ffdf object
value  a new filename
...  dummy to keep R CMD CHECK quiet

Details

Assigning a filename<- means renaming the corresponding file on disk - even for ram objects. If that fails, the assignment fails. If a file is moved in or out of getOption("fftempdir") the finalizer is changed accordingly to 'delete' in getOption("fftempdir") and 'close' otherwise. A pattern is an incomplete filename (optional path and optional filename-prefix) that is turned to filenames by adding a random string using and optionally an extension from optionally an extension from getOption("ffextension") (see fftempfile). filename<- exhibits R's standard behaviour of considering "filename" and "/filename" both to be located in getwd. By constrast pattern<- will create "filename" without path in getOption("fftempdir") and only "/filename" in getwd.

Value

filename and pattern return a character filename or pattern. For ffdf returns a list with one filename element for each physical component. The assignment functions return the changed object, which will keep the change even without re-assigning the return-value

Author(s)

Jens Oehlschlägel

See Also

fftempfile, finalizer, ff, as.ff, as.ram, update.ff, file.move

Examples

## Not run:
message("Neither giving pattern nor filename gives a random filename with extension ffextension in fftempdir")
x <- ff(1:12)
finalizer(x)
filename(x)
message("Giving a pattern with just a prefix moves to a random filename beginning with the prefix in fftempdir")
pattern(x) <- "myprefix_"
filename(x)
message("Giving a pattern with a path and prefix moves to a random filename beginning with prefix in path (use . for getwd) ")
pattern(x) <- "./myprefix"
filename(x)
message("Giving a filename moves to exactly this filename and extension in the R-expected place) ")
if (!file.exists("./myfilename.myextension")){
finalize(x) <- "./myfilename.myextension"
filename(x)
)

message("NOTE that the finalizer has changed from 'delete' to 'close':
now we are responsible for deleting the file - NOT the finalizer")
finalizer(x)
delete(x)
rm(x)

## End(Not run)

finalize

Call finalizer

Description
This calls the currently assigned finalizer, either via R’s finalization mechanism or manually.

Usage
finalize(x, ...)
## S3 method for class 'ff_pointer'
finalize(x, ...)
## S3 method for class 'ff'
finalize(x, ...)
## S3 method for class 'ffdf'
finalize(x, ...)

Arguments
x either an ff or ffdf object or an ff_pointer, see details
...
currently ignored

Details
The finalize.ff_pointer method is called from R after it had been passed to reg.finalizer. It will set the finalizer name to NULL and call the finalizer.
The finalize generic can be called manually on ff or ffdf objects. It will call the finalizer but not touch the finalizer name.
For more details see finalize

Value
returns whatever the called finalizer returns, for ffdf a list with the finalization returns of each physical component is returned.
Note

finalize.ff_pointer MUST NEVER be called manually - neither directly nor by calling the
generic on an ff_pointer (could erroneously signal that there is no pending finalization lurking
around)

finalizer

Get and set finalizer (name)

Description

The generic finalizer allows to get the current finalizer. The generic finalizer<- allows to set
the current finalizer or to change an existing finalizer (but not to remove a finalizer).

Usage

finalizer(x, ...)
finalizer(x, ...) <- value
## S3 method for class 'ff'
finalizer(x, ...)

## S3 replacement method for class 'ff'
```rinalizer(x, ...) <- value
```

### Arguments
- **x**: an ff object
- **value**: the name of the new finalizer
- **...**: ignored

### Details
If an ff object is created a finalizer is assigned, it has the task to free resources no longer needed, for example remove the ff file or free the C++ RAM associated with an open ff file. The assigned finalizer depends on the location of the ff file: if the file is created in `getOption(fftempdir)` it is considered temporary and has default finalizer `delete`, files created in other locations have default finalizer `close`. The user can override this either by setting options("fffinalizer") or by using argument `finalizer` when creating single ff objects. Available finalizer generics are "close", "delete" and "deleteIfOpen", available methods are `close.ff`, `delete.ff` and `deleteIfOpen.ff`. In order to be able to change the finalizer before finalization, the finalizer is NOT directly passed to R’s finalization mechanism `reg.finalizer` (an active finalizer can never be changed other than be executed). Instead the NAME of the desired finalizer is stored in the ff object and `finalize.ff_pointer` is passed to `reg.finalizer`. `finalize.ff_pointer` will at finalization-time determine the desired finalizer and call it.

There are two possible triggers for execution `finalize.ff_pointer`:

1. the garbage collection `gc` following removal `rm` of the ff object
2. closing R if `finonexit` was `TRUE` at ff creation-time, determined by options("fffinonexit")

Furthermore there are two possible triggers for calling the finalizer

1. an explicit call to `finalize`
2. an explicit call to one of the finalizers `close`, `delete` and `deleteIfOpen`

The user can define custom finalizers by creating a generic function like `delete`, a `ff_pointer` method like `delete.ff_pointer` and a ff method for manual calls like `delete.ff`. The user then is responsible to take care of two things

1. adequate freeing of resources
2. proper maintenance of the finalizer name in the ff object via `physical$finalizer`

`is.null(finalizer(ff))` indicates NO active finalizer, i.e. no pending execution of `finalize.ff_pointer` lurking around after call of `reg.finalizer`. This requires that

1. the `ff_pointer` method sets the finalizer name to `NULL`
2. the ff may change a non-NULL finalizer name to a different name but not change it to `NULL`
Value

finalizer returns the name of the active finalizer or NULL if no finalizer is active.
finalizer<- returns the changed ff object (reassignment of this return value not needed to keep
the change). If there was no pending call to finalize.ff_pointer (is.null(finalizer(ff)),
finalizer<- will create one by calling reg.finalizer with the current setting of physical$finonexit.

Note

You can not assign NULL to an active finalizer using finalizer<- because this would not stop R’s
finalization mechanism and would carry the risk of assigning MULTIPLE finalization tasks.

rm(x)
file.exists(fnam)
gc()
file.exists(fnam)

Description

Check if an object has fixed diagonal

Usage

fixdiag(x, ...)
fixdiag(x, ...) <- value
## S3 method for class 'ff'
fixdiag(x, ...)
## Default S3 method:
fixdiag(x, ...)
## S3 method for class 'dist'
fixdiag(x, ...)

fixdiag

Test for fixed diagonal
Arguments

x  an ff or ram object
value  assignment value
...  further arguments (not used)

Details

ff symmetric matrices can be declared to have fixed diagonal at creation time. Compatibility function fixdiag.default returns NULL, fixdiag.dist returns 0.

Value

NULL or the scalar representing the fixed diagonal

Author(s)

Jens Oehlschlägel

See Also

fixdiag, ff, dist

Examples

fixdiag(matrix(1:16, 4, 4))
fixdiag(dist(rnorm(1:4)))

geterror.ff  Get error and error string

Description

Get last error code and error string that occurred on an ff object.

Usage

gterror.ff(x)
geterrstr.ff(x)

Arguments

x  an ff object

Value

gterror.ff returns an error integer code (no error = 0) and geterrstr.ff returns the error message (no error = "no error").
Description

The function is used for obtaining the natural OS-specific page size in Bytes. `getpagesize` returns the OS-specific page size in Bytes for memory mapped files, while `getdefaultpagesize` returns a suggested page size. `getalignedpagesize` returns the pagesize as a multiple of the OS-specific page size in Bytes, which is the correct way to specify pagesize in ff.

Usage

```r
getpagesize()
getdefaultpagesize()
getalignedpagesize(pagesize)
```

Arguments

`pagesize` a desired pagesize in bytes

Value

An integer giving the page size in Bytes.

Author(s)

Daniel Adler, Jens Oehlschlägel

Examples

```r
getpagesize()
getdefaultpagesize()
getalignedpagesize(2000000)
```
**getset.ff**

Reading and writing vectors of values (low-level)

**Description**

The three functions `get.ff`, `set.ff` and `getset.ff` provide the simplest interface to access an ff file: getting and setting vector of values identified by positive subscripts

**Usage**

```r
get.ff(x, i)
set.ff(x, i, value, add = FALSE)
getset.ff(x, i, value, add = FALSE)
```

**Arguments**

- `x` an ff object
- `i` an index position within the ff file
- `value` the value to write to position `i`
- `add` TRUE if the value should rather increment than overwrite at the index position

**Details**

`getset.ff` combines the effects of `get.ff` and `set.ff` in a single operation: it retrieves the old value at position `i` before changing it. `getset.ff` will maintain `na.count`.

**Value**

- `get.ff` returns a vector, `set.ff` returns the 'changed' ff object (like all assignment functions do) and `getset.ff` returns the value at the subscript positions. More precisely `getset.ff(x, i, value, add = FALSE)` returns the old values at the subscript positions `i` while `getset.ff(x, i, value, add = TRUE)` returns the incremented values at the subscript positions.

**Note**

`get.ff`, `set.ff` and `getset.ff` are low level functions that do not support `ramclass` and `ramattrs` and thus will not give the expected result with factor and POSIXct

**Author(s)**

Jens Oehlschlägel

**See Also**

`readwrite.ff` for low-level access to contiguous chunks and `[..ff` for high-level access
Examples

```r
x <- ff(0, length=12)
get.ff(x, 3L)
set.ff(x, 3L, 1)
x
set.ff(x, 3L, 1, add=TRUE)
x
getset.ff(x, 3L, 1, add=TRUE)
getset.ff(x, 3L, 1)
x
rm(x); gc()
```

---

**hi**  
**Hybrid index class**

Description

Class for hybrid index representation, plain and rle-packed

Usage

```r
hi(from, to, by = 1L, maxindex = NA, vw = NULL, pack = TRUE, NAs = NULL)
## S3 method for class 'hi'
print(x, ...)
## S3 method for class 'hi'
str(object, nest.lev=0, ...)
```

Arguments

- `from` integer vector of lower sequence bounds
- `to` integer vector of upper sequence bounds
- `by` integer of stepsizes
- `maxindex` maximum indep position (needed for negative indices)
- `vw` virtual window information, see `vw`
- `pack` FALSE to suppress rle-packing
- `NAs` a vector of NA positions (not yet used)
- `x` an object of class 'hi' to be printed
- `object` an object of class 'hi' to be str'ed
- `nest.lev` current nesting level in the recursive calls to str
- `...` further arguments passed to the next method
Details

Class `hi` will represent index data either as a plain positive or negative index vector or as an rle-packed version thereof. The current implementation switches from plain index positions `i` to rle-packed storage of `diff(i)` as soon as the compression ratio is 3 or higher. Note that sequences shorter than 2 must never be packed (could cause C-side crash). Furthermore hybrid indices are guaranteed to be sorted ascending, which helps `ffs` access method avoiding to swap repeatedly over the same memory pages (or file positions).

Value

A list of class 'hi' with components

- `x` directly accessed by the C-code: the sorted index of class 'rlepack' as returned by `rlepack`
- `ix` NULL or positions to restore original order
- `re` logical scalar indicating if sequence was reversed from descending to ascending (in this case `is.null(ix)`)  
- `minindex` directly accessed by the C-code: represents the lowest positive subscript to be enumerated in case of negative subscripts
- `maxindex` directly accessed by the C-code: represents the highest positive subscript to be enumerated in case of negative subscripts
- `length` number of subscripts, whether negative or positive, not the number of selected elements
- `dim` NULL or dim – used by `as.matrix.hi`
- `dimorder` NULL or `dimorder`
- `symmetric` logical scalar indicating whether we have a symmetric matrix
- `fixdiag` logical scalar indicating whether we have a fixed diagonal (can only be true for symmetric matrices)
- `vw` virtual window information `vw`
- `NAs` NULL or NA positions as returned by `rlepack`

Note

`hi` defines the class structure, however usually `as.hi` is used to acturally Hybrid Index Preprocessing for `ff`

Author(s)

Jens Oehlschlägel

See Also

`as.hi` for coercion, `rlepack`, `intrle`, `maxindex`, `poslength`

Examples

```r
hi(c(1, 11, 29), c(9, 19, 21), c(1,1,-2))
as.integer(hi(c(1, 11, 29), c(9, 19, 21), c(1,1,-2)))
```
hiparse  

Hybrid Index, parsing

Description

hiparse implements the parsing done in Hybrid Index Preprocessing in order to avoid RAM for expanding index expressions. Not to be called directly.

Usage

hiparse(x, envir, first = NA_integer_, last = NA_integer_)

Arguments

x  
an index expression, precisely: call

envir  
the environment in which to evaluate components of the index expression

first  
first index position found so far

last  
last index position found so far

Details

This primitive parser recognises the following tokens: numbers like 1, symbols like x, the colon sequence operator : and the concat operator c. hiparse will Recall until the index expression is parsed or an unknown token is found. If an unknown token is found, hiparse evaluates it, inspects it and either accepts it or throws an error, caught by as.hi.call, which falls back to evaluating the index expression and dispatching (again) an appropriate as.hi method. Reasons for suspending the parsing: if the inspected token is of class 'hi', 'ri', 'bit', 'bitwhich', 'is.logical', 'is.character', 'is.matrix' or has length>16.

Value

undefined (and redefined as needed by as.hi.call)

Author(s)

Jens Oehlschlägel

Jens Oehlschlägel

See Also
inherits, as.ff, is.ffdf

Examples
is.ff(integer())

---

is.ffdf  

Description
checks if x inherits from class "ffdf"

Usage
is.ffdf(x)

Arguments
x any object
is.open

Value

logical scalar

Author(s)

Jens Oehlschlägel

See Also

inherits, as.ffdf, is.ff

Examples

is.ffdf(integer())

is.open is.ffdf Test if object is opened

Description

Test whether an ff or ffdf object or a ff_pointer is opened.

Usage

is.open(x, ...)
## S3 method for class 'ff'
is.open(x, ...)
## S3 method for class 'ffdf'
is.open(x, ...)
## S3 method for class 'ff_pointer'
is.open(x, ...)

Arguments

x an ff or ffdf object
...

Details

ff objects open automatically if accessed while closed. For ffdf objects we test all of their physical components including their row.names if they are is.ff

Value

TRUE or FALSE (or NA if not all components of an ffdf object are opened or closed)
is.readonly

Author(s)
Jens Oehlschlägel

See Also
is.readonly, open.ff, close.ff

Examples
x <- ff(1:12)
is.open(x)
close(x)
is.open(x)
rm(x); gc()

is.readonly Get readonly status

Description
Get readonly status of an ff object

Usage
is.readonly(x, ...)
## S3 method for class 'ff'
is.readonly(x, ...)

Arguments
x x
...

Details
ff objects can be created/opened with readonly=TRUE. After each opening of the ff file readonly status is stored in the physical attributes and serves as the default for the next opening. Thus querying a closed ff object gives the last readonly status.

Value
logical scalar

Author(s)
Jens Oehlschlägel
See Also

open.ff, physical

Examples

```r
x <- ff(1:12)
is.readonly(x)
close(x)
open(x, readonly=TRUE)
is.readonly(x)
close(x)
is.readonly(x)
rm(x)
```

Description

Functions to mark an ff or ram object as `is.sorted` and query this. Responsibility to maintain this attribute is with the user.

Usage

```r
## Default S3 method:
is.sorted(x, ...)
## Default S3 replacement method:
is.sorted(x, ...) <- value
```

Arguments

- `x`: an ff or ram object
- `...`: ignored
- `value`: NULL (to remove the `is.sorted` attribute) or TRUE or FALSE

Details

Sorting is slow, see `sort`. Checking whether an object is sorted can avoid unnessary sorting – see `is.unsorted, intisasc` – but still takes too much time with large objects stored on disk. Thus it makes sense to maintain an attribute, that tells us whether sorting can be skipped. Note that – though you change it yourself – `is.sorted` is a physical attribute of an object, because it represents an attribute of the data, which is shared between different virtual views of the object.

Value

TRUE (if set to TRUE) or FALSE (if set to NULL or FALSE)
Note

ff will set is.sorted(x) <- FALSE if clone or length<-.ff have increased length.

Author(s)

Jens Oehlschlägel

See Also

is.ordered.ff for testing factor levels, is.unsorted for testing the data, intisasc for a quick version thereof, na.count for yet another physical attribute

Examples

```r
x <- 1:12
is.sorted(x) <- !(is.na(is.unsorted(x)) || is.unsorted(x))
is.sorted(x)
x[1] <- 100L
message("don't forget to maintain once it's no longer TRUE")
is.sorted(x) <- FALSE
message("check whether as 'is.sorted' attribute is maintained")
!is.null(physical(x)$is.sorted)
message("remove the 'is.sorted' attribute")
is.sorted(x) <- NULL
message("NOTE that querying 'is.sorted' still returns FALSE")
is.sorted(x)
```

Description

Gets and sets length of ff objects.

Usage

```r
## S3 method for class 'ff'
length(x)
## S3 replacement method for class 'ff'
length(x) <- value
```

Arguments

- `x` object to query
- `value` new object length
length.ffdf

Details
Changing the length of ff objects is only allowed if no \texttt{vw} is used. Changing the length of ff objects will remove any \texttt{dim.ff} and \texttt{dimnames.ff} attribute. Changing the length of ff objects will remove any \texttt{na.count} or \texttt{is.sorted} attribute and warn about this. New elements are usually zero, but it may depend on OS and filesystem what they really are. If you want standard R behaviour: filling with NA, you need to do this yourself. As an exception to this rule, ff objects with \texttt{names.ff} will be filled with NA's automatically, and the length of the names will be adjusted (filled with position numbers where needed, which can easily consume a lot of RAM, therefore removing 'names' will help to faster increase length without RAM problems).

Value
Integer scalar

Note
Special care needs to be taken with regard ff objects that represent factors. For ff factors based on UNSIGNED \texttt{vmodes}, new values of zero are silently interpreted as the first factor level. For ff factors based on SIGNED \texttt{vmodes}, new values of zero result in illegal factor levels. See \texttt{nrow<-.}

Author(s)
Jens Oehlschlägel

See Also
\texttt{length, maxlength, file.resize, dim, virtual}

Examples
\begin{verbatim}
x <- ff(1:12)
maxlength(x)
length(x)
length(x) <- 10
maxlength(x)
length(x)
length(x) <- 16
maxlength(x)
length(x)
rm(x); gc()
\end{verbatim}

---

| length.ffdf | Getting length of a \texttt{ffdf} dataframe |

Description
Getting "length" (number of columns) of a \texttt{ffdf} dataframe
length.hi

Usage

## S3 method for class 'ffdf'
length(x)

Arguments

x an ffdf object

Value

integer number of columns

Author(s)

Jens Oehlschlägel

See Also

dim.ffdf, length.ff, ffdf

Examples

length(as.ffdf(data.frame(a=1:26, b=letters, stringsAsFactors=TRUE)))
gc()

length.hi

Hybrid Index, querying

Description

Functions to query some index attributes

Usage

## S3 method for class 'hi'
length(x)
## S3 method for class 'hi'
maxindex(x, ...)
## S3 method for class 'hi'
poslength(x, ...)

Arguments

x an object of class hi
...
further arguments (not used)
Details

length.hi returns the number of the subscript elements in the index (even if they are negative).
By contrast poslength returns the number of selected elements (which for negative indices is
maxindex(x) - length(unique(x)). maxindex returns the highest possible index position.

Value

an integer scalar

Note

duplicated negative indices are removed

Author(s)

Jens Oehlschlägel

See Also

hi, as.hi, length.ff, length, poslength, maxindex

Examples

length(as.hi(-1, maxindex=12))
poslength(as.hi(-1, maxindex=12))
maxindex(as.hi(-1, maxindex=12))
message("note that")
length(as.hi(c(-1, -1), maxindex=12))
length(as.hi(c(1,1), maxindex=12))

levels.ff

Getting and setting factor levels

Description

levels.ff<- sets factor levels, levels.ff gets factor levels

Usage

## S3 method for class 'ff'
levels(x)
## S3 replacement method for class 'ff'
levels(x) <- value
  is.factor(x)
  is.ordered(x)
## S3 method for class 'ff'
is.factor(x)
## S3 method for class 'ff'

is.ordered(x)
## Default S3 method:
is.factor(x)
## Default S3 method:
is.ordered(x)

Arguments

x an ff object
value the new factor levels, if NA is an allowed level it needs to be given explicitly,
nothing is excluded

Details

The ff object must have an integer vmode, see .rammode. If the mode is unsigned – see .vunsigned
– the first factor level is coded with 0L instead of 1L in order to maximize the number of codable
levels. Usually the internal ff coding – see ram2ffcode – is invisible to the user: when subscripting
from an ff factor, unsigend codings are automatically converted to R’s standard factor codes starting
at 1L. However, you need to be aware of the internal ff coding in two situations.
1. If you convert an ff integer object to an ff factor object and vice versa by assigning levels and
is.null(oldlevels)!is.null(newlevels).
2. Assigning data that does not match any level usually results in NA, however, in unsigned types
there is no NA and all unknown data are mapped to the first level.

Value

levels returns a character vector of levels (possibly including as.character(NA)).

Note

When levels as assigned to an ff object that formerly had not levels, we assign automatically
ramclass == “factor”. If you want to change to an ordered factor, use virtual$ramclass <-c("ordered","factor")

Author(s)

Jens Oehlschlägel

See Also

Examples

message("--- create an ff factor including NA as last level")
x <- ff("a", levels=c(letters, NA), length=99)
message(" we expect a warning because "A" is an unknown level")
x[] <- c("a", NA, "A")
x
levels(x)
message("--- create an ff ordered factor")
x <- ff(letters, levels=letters, ramclass=c("ordered","factor"), length=260)
x
levels(x)

message(" make it a non-ordered factor")
virtual(x)$ramclass <- "factor"
x
rm(x); gc()

## Not run: 
message("--- create an unsigned quad factor")
x <- ff(c("A","T","G","C"), levels=c("A","T","G","C"), vmode="quad", length=100)
x
message(" 0:3 coding usually invisible to the user")
unclass(x[1:4])
message(" after removing levels, the 0:3 coding becomes visible to the user")
message(" we expect a warning here")
levels(x) <- NULL
x[1:4]
rm(x); gc()

## End(Not run)

---

**ff Limitations and Warnings**

**Description**

This help page lists the currently known limitations of package ff, as well as differences between ff and ram methods.

**Automatic file removal**

Remind that not giving parameter `ff(filename=)` will result in a temporary file in `fftempdir` with 'delete' finalizer, while giving parameter `ff(filename=)` will result in a permanent file with 'close' finalizer. Do avoid setting `setwd(getOption("fftempdir"))`! Make sure you really understand the implications of automatic unlinking of `getOption("fftempdir")`.**onunload**, of finalizer choice and of finalizing behaviour at the end of R sessions as defaulted in `getOption("fffinonexit")`. **Otherwise you might experience 'unexpected' losses of files and data.**

**Size of objects**

*ff* objects can have length zero and are limited to `.Machine$integer.max` elements. We have not yet ported the R code to support 64bit double indices (in essence 52 bits integer) although the C++ back-end has been prepared for this. Furthermore filesize limitations of the OS apply, see *ff*. 
Side effects

In contrast to standard R expressions, ff expressions violate the functional programming logic and are called for their side effects. This is also true for ram compatibility functions `swap.default`, and `add.default`.

Hybrid copying semantics

If you modify a copy of an ff object, changes of data ([<]) and of physical attributes will be shared, but changes in virtual and class attributes will not.

Limits of compatibility between ff and ram objects

If it’s not too big, you can move an ff object completely into R’s RAM through `as.ram`. However, you should watch out for three limitations:

1. Ram objects don’t have hybrid copying semantics; changes to a copy of a ram object will never change the original ram object
2. Assigning values to a ram object can easily upgrade to a higher storage.mode. This will create conflicts with the vmode of the ram object, which goes undetected until you try to write back to disk through `as.ff`.
3. Writing back to disk with `as.ff` under the same filename requires that the original ff object has been deleted (or at least closed if you specify parameter overwrite=TRUE).

Index expressions

ff index expressions do not allow zeros and NAs, see see `.[.ff` and see `as.hi`

Availability of bydim parameter

Parameter bydim is only available in ff access methods, see `.[.ff`

Availability of add parameter

Parameter add is only available in ff access methods, see `.[.ff`

Compatibility of swap and add

If index expressions contain duplicated positions, the ff and ram methods for `swap` and `add` will behave differently, see `swap`.

Definition of [ and [<-:

You should consider the behaviour of `.[.ff` and `[[<-.ff` as undefined and not use them in programming. Currently they are shortcuts to `get.ff` and `set.ff`, which unlike `.[.ff` and `[[<-.ff` do not support factor and POSIXct, nor dimorder or virtual windows vw. In contrast to the standard methods, `.[.ff` and `[[<-.ff` only accepts positive integer index positions. The definition of `.[.ff` and `[[<-.ff` may be changed in the future.
Multiple vector interpretation in arrays

R objects have always standard `dimorder` seq_along(dim). In case of non-standard dimorder (see `dimorderStandard`) the vector sequence of array elements in R and in the ff file differs. To access array elements in file order, you can use `getset.ff`, `readwrite.ff` or copy the ff object and set `dim(ff)<-NULL` to get a vector view into the ff object (using `[` dispatches the vector method `[.ff`). To access the array elements in R standard dimorder you simply use `[` which dispatches to `[.ff_array`. Note that in this case `as.hi` will unpack the complete index, see next section.

RAM expansion of index expressions

Some index expressions do not consume RAM due to the `hi` representation. For example `1:n` will almost consume no RAM however large `n`. However, some index expressions are expanded and require to `maxindex(i) * .rambytes["integer"]` bytes, either because the sorted sequence of index positions cannot be rle-packed efficiently or because `hiparse` cannot yet parse such expression and falls back to evaluating/expanding the index expression. If the index positions are not sorted, the index will be expanded and a second vector is needed to store the information for re-ordering, thus the index requires `2 * maxindex(i) * .rambytes["integer"]` bytes.

RAM expansion when recycling assignment values

Some assignment expressions do not consume RAM for recycling. For example `x[1:n] <-1:k` will not consume RAM however large is `n` compared to `k`, when `x` has standard `dimorder`. However, if `length(value)>1`, assignment expressions with non-ascending index positions trigger recycling the value R-side to the full index length. This will happen if `dimorder` does not match parameter `bydim` or if the index is not sorted in ascending order.

Byteorder incompatibility

Note that ff files cannot been transferred between systems with different byteorder.

---

**matcomb**

**Array: make matrix indices from row and columns positions**

**Description**

create matrix indices from row and columns positions

**Usage**

`matcomb(r, c)`

**Arguments**

- `r` integer vector of row positions
- `c` integer vector of column positions
\textit{matprint}  

\textbf{Details}  
rows rotate faster than columns  

\textbf{Value}  
a \( k \) by 2 matrix of matrix indices where \( k = \text{length}(r) \times \text{length}(c) \)  

\textbf{Author(s)}  
Jens Oehlschlägel  

\textbf{See Also}  
row, col, expand.grid  

\textbf{Examples}  
\begin{verbatim}
matcomb(1:3, 1:4)
matcomb(2:3, 2:4)
\end{verbatim}  

\begin{verbatim}
matprint
\end{verbatim}  

\textit{Print beginning and end of big matrix}  

\textbf{Description}  
Print beginning and end of big matrix  

\textbf{Usage}  
\begin{verbatim}
matprint(x, maxdim = c(16, 16), digits = getOption("digits"))
## S3 method for class 'matprint'
print(x, quote = FALSE, right = TRUE, ...)  
\end{verbatim}  

\textbf{Arguments}  
\begin{verbatim}
x a matrix
maxdim max number of rows and columns for printing
digits see format
quote see print
right see print
... see print
\end{verbatim}
Value

A list of class 'matprint' with components

- subscript: A list with four vectors of subscripts: row begin, column begin, row end, column end
- example: The extracted example matrix as character including separators
- rsep: Logical scalar indicating whether row separator is included
- csep: Logical scalar indicating whether column separator is included

Author(s)

Jens Oehlschlägel

See Also

vecprint

Examples

matprint(matrix(1:(300*400), 300, 400))

---

**maxffmode**

*Lossless vmode coercability*

Description

maxffmode returns the lowest vmode that can absorb all input vmodes without data loss

Usage

maxffmode(...)

Arguments

... one or more vectors of vmodes

Value

The smallest .ffmode which can absorb the input vmodes without data loss

Note

The output can be larger than any of the inputs (if the highest input vmode is an integer type without NA and any other input requires NA).

Author(s)

Jens Oehlschlägel
See Also

`.vcoerceable`, `.ffmode`, `.ffconform`

Examples

```r
maxffmode(c("quad","logical"), "ushort")
```

---

`maxlength`  
*Get physical length of an ff or ram object*

Description

`maxlength` returns the physical length of an ff or ram object

Usage

```r
maxlength(x, 
```  
```
## S3 method for class 'ff'
maxlength(x, 
```  
```
## Default S3 method:
maxlength(x, 
```  
```
Arguments

- `x`  
  ff or ram object
- `...`  
  additional arguments (not used)

Value

integer scalar

Author(s)

Jens Oehlschlägel

See Also

`length.ff`, `maxindex`

Examples

```r
x <- ff(1:12)
length(x) <- 10
length(x)
maxlength(x)
x
rm(x); gc()
```
mismatch

Test for recycle mismatch

Description

mismatch will return TRUE if the larger of nx, ny is not a multiple of the other and the other is >0 (see arithmetic.c). ymismatch will return TRUE if nx is not a multiple of ny and ny>0

Usage

mismatch(nx, ny)

ymismatch(nx, ny)

Arguments

nx x length
ny y length

Value

logical scalar

Author(s)

Jens Oehlschlägel

See Also

ffconform

Examples

ymismatch(4,0)
ymismatch(4,2)
ymismatch(4,3)
ymismatch(2,4)
mismatch(4,0)
mismatch(4,2)
mismatch(4,3)
mismatch(2,4)
na.count

Getting and setting 'na.count' physical attribute

Description

The 'na.count' physical attribute gives the current number of NAs if properly initialized and properly maintained, see details.

Usage

## S3 method for class 'ff'
na.count(x, ...)
## Default S3 method:
na.count(x, ...)
## S3 replacement method for class 'ff'
na.count(x, ...) <- value
## Default S3 replacement method:
na.count(x, ...) <- value

Arguments

x an ff or ram object
...
value NULL (to remove the 'na.count' attribute) or TRUE to activate or an integer value

Details

The 'na.count' feature is activated by assigning the current number of NAs to na.count(x) <- currentNA and deactivated by assigning NULL. The 'na.count' feature is maintained by the, getset.ff, readwrite.ff and swap, other ff methods for writing – set.ff, [[<-ff, write.ff, [<-ff – will stop if 'na.count' is activated. The functions na.count and na.count<- are generic. For ram objects, the default method for na.count calculates the number of NAs on the fly, thus no maintenance restrictions apply.

Value

NA (if set to NULL or NA) or an integer value otherwise

Author(s)

Jens Oehlschlägel, Daniel Adler (C++ back-end)

See Also

getset.ff, readwrite.ff and swap for methods that support maintenance of 'na.count', NA, is.sorted for yet another physical attribute
Examples

```r
message("--- ff examples ---")
x <- ff(1:12)
na.count(x)
message("activate the 'na.count' physical attribute and set the current na.count manually")
na.count(x) <- 0L
message("add one NA with a method that maintains na.count")
swap(x, NA, 1)
na.count(x)
message("remove the 'na.count' physical attribute (and stop automatic maintenance")
na.count(x) <- NULL
message("activate the 'na.count' physical attribute and have ff automatically calculate the current na.count")
na.count(x) <- TRUE
na.count(x)
message("--- ram examples ---")
x <- 1:12
na.count(x)
x[1] <- NA
message("activate the 'na.count' physical attribute and have R automatically calculate the current na.count")
na.count(x) <- TRUE
na.count(x)
message("remove the 'na.count' physical attribute (and stop automatic maintenance")
na.count(x) <- NULL
na.count(x)
rm(x); gc()
```

names.ff

*Getting and setting names*

Description

For `ff_vectors` you can set names, though this is not recommended for large objects.

Usage

```r
## S3 method for class 'ff'
names(x)
## S3 replacement method for class 'ff'
names(x) <- value
## S3 method for class 'ff_array'
names(x)
## S3 replacement method for class 'ff_array'
names(x) <- value
```

Arguments

- `x` a `ff` vector
- `value` a character vector
Details

If `vw` is set, `names.ff` returns the appropriate part of the names, but you can’t set names while `vw` is set. `names.ff_array` returns NULL and setting names for `ff_array`s is not allowed, but setting `dimnames` is.

Value

`names` returns a character vector (or NULL)

Author(s)

Jens Oehlschlägel

See Also

`names`, `dimnames.ff_array`, `vw`, `virtual`

Examples

```r
x <- ff(1:26, names=letters)
names(x)
names(x) <- LETTERS
names(x)
names(x) <- NULL
names(x)
rm(x); gc()
```

\section*{Description}

Function `nrow<-` assigns `dim` with a new number of rows.
Function `ncol<-` assigns `dim` with a new number of columns.

Usage

```r
nrow(x) <- value
ncol(x) <- value
```

Arguments

- `x` a object that has `dim` AND can be assigned ONE new dimension
- `value` the new size of the assigned dimension

Details

Currently only assigning new rows to `ffdf` is supported. The new `ffdf` rows are not initialized (usually become zero). NOTE that
Value

The object with a modified dimension

Author(s)

Jens Oehlschlägel

See Also

ffdf, dim.ffdf

Examples

```r
a <- as.ff(1:26)
b <- as.ff(factor(letters), vmode="integer")
c <- as.ff(factor(letters), vmode="ubyte")
df <- ffdf(a,b,c)
nrow(df) <- 2*26
df
message("NOTE that the new rows have silently the first level 'a' for UNSIGNED vmodes")
message("NOTE that the new rows have an illegal factor level <0> for SIGNED vmodes")
message("It is your responsibility to put meaningful content here")
message("As an example we replace the illegal zeros by NA")
df$b[27:52] <- NA
df
rm(a,b,c,df); gc()
```

---

open.ff  

*Opening an ff file*

Description

open.ff opens an ff file, optionally marking it readonly and optionally specifying a caching scheme.

Usage

```r
## S3 method for class 'ff'
open(con, readonly = FALSE, pagesize = NULL, caching = NULL, assert = FALSE, ...)
## S3 method for class 'ffdf'
open(con, readonly = FALSE, pagesize = NULL, caching = NULL, assert = FALSE, ...)
```

Arguments

- `con`: an ff or ffdf object
- `readonly`: readonly
- `pagesize`: number of bytes to use as pagesize or NULL to take the pagesize stored in the physical attribute of the ff object, see *getalignedpagesize*
caching one of 'mmnoflush' or 'mmeachflush', see \texttt{ff}
assert setting this to TRUE will give a message if the \texttt{ff} was not open already
...
        further arguments (not used)

Details

\texttt{ff} objects will be opened automatically when accessing their content and the file is still closed. Opening \texttt{ffdf} objects will open all of their \texttt{physical} components including their \texttt{row.names} if they are \texttt{is.ff}

Value

TRUE if object could be opened, FALSE if it was opened already (or NA if not all components of an \texttt{ffdf} returned FALSE or TRUE on opening)

Author(s)

Jens Oehlschlägel

getpagesize

Examples

x <- ff(1:12)
pagesize(x)

physical.ff

Getting and setting physical and virtual attributes of ff objects

Description

Functions for getting and setting physical and virtual attributes of ff objects.

Usage

## S3 method for class 'ff'
physical(x)
## S3 method for class 'ff'
virtual(x)
## S3 replacement method for class 'ff'
physical(x) <- value
## S3 replacement method for class 'ff'
virtual(x) <- value
**Arguments**

- **x**: an ff object
- **value**: a list with named elements

**Details**

ff objects have physical and virtual attributes, which have different copying semantics: physical attributes are shared between copies of ff objects while virtual attributes might differ between copies. `as.ram` will retain some physical and virtual attributes in the ram clone, such that `as.ff` can restore an ff object with the same attributes.

**Value**

`physical` and `virtual` returns a list with named elements.

**Author(s)**

Jens Oehlschlägel

**See Also**

- `physical`, `physical.ffdf`, `ff`, `as.ram`;
- `is.sorted` and `na.count` for applications of physical attributes;
- `levels.ff` and `ramattrs` for applications of virtual attributes

**Examples**

```r
x <- ff(1:12)
x
physical(x)
virtual(x)
y <- as.ram(x)
physical(y)
virtual(y)
rm(x,y); gc()
```

---

**Description**

Functions for getting physical and virtual attributes of ffdf objects.

**Usage**

```r
# S3 method for class 'ffdf'
physical(x)

# S3 method for class 'ffdf'
virtual(x)
```
Arguments

x an ffdf object

Details

ffdf objects enjoy a complete decoupling of virtual behaviour from physical storage. The physical component is simply a (potentially named) list where each element represents an atomic ff vector or matrix. The virtual component is itself a dataframe, each row of which defines a column of the ffdf through a mapping to the physical component.

Value

'physical.ffdf' returns a list with atomic ff objects.
'virtual.ffdf' returns a data.frame with the following columns

- VirtualVmode the vmode of this row (=ffdf column)
- AsIs logical defining the AsIs status of this row (=ffdf column)
- VirtualIsMatrix logical defining whether this row (=ffdf column) represents a matrix
- PhysicalIsMatrix logical reporting whether the corresponding physical element is a matrix
- PhysicalElementNo integer identifying the corresponding physical element
- PhysicalFirstCol integer identifying the first column of the corresponding physical element (1 if it is not a matrix)
- PhysicalLastCol integer identifying the last column of the corresponding physical element (1 if it is not a matrix)

Examples

x <- 1:2
y <- matrix(1:4, 2, 2)
z <- matrix(1:4, 2, 2)

message("Here the y matrix is first converted to single columns by data.frame, then those columns become ff")
d <- as.ffdf(data.frame(x=x, y=y, z=I(z)))
physical(d)
virtual(d)

message("Here the y matrix is first converted to ff, and then stored still as matrix in the ffdf object (although virtually treated as columns of ffdf)")

d <- ffdf(x=as.ff(x), y=as.ff(y), z=I(as.ff(z)))

physical(d)

virtual(d)

message("Apply the usual methods extracting physical attributes")
lapply(physical(d), filename)
lapply(physical(d), vmode)
message("And don't confuse with virtual vmode")

vmode(d)

rm(d); gc()

---

print.ff  

**Print and str methods**

**Description**

printing ff objects and compactly showing their structure

**Usage**

```r
## S3 method for class 'ff'
print(x, ...)
## S3 method for class 'ff_vector'
print(x, maxlength = 16, ...)
## S3 method for class 'ff_matrix'
print(x, maxdim = c(16, 16), ...)
## S3 method for class 'ff'
str(object, nest.lev=0, ...)
## S3 method for class 'ffdf'
str(object, nest.lev=0, ...)
```

**Arguments**

- `x` a ff object
- `object` a ff object
- `nest.lev` current nesting level in the recursive calls to `str`
- `maxlength` max number of elements to print from an `ff_vector`
- `maxdim` max number of elements to print from each dimension from an `ff_array`
- `...` further arguments to print

**Details**

The print methods just print a few exemplary elements from the beginning and end of the dimensions.
**Value**

`invisible()`

**Author(s)**

Jens Oehlschlägel

**See Also**

`ff`, `print`, `str`  

**Examples**

```r
x <- ff(1:10000)
print(x, maxlength=30)
dim(x) <- c(100,100)
x
rm(x); gc()
```

---

**Description**

Function `ram2ffcode` creates the internal factor codes used by `ff` to store factor levels. Function `ram2ramcode` is a compatibility function used instead if `RETURN_FF==FALSE`.

**Usage**

```r
ram2ffcode(value, levels, vmode)
ram2ramcode(value, levels)
```

**Arguments**

- `value`: factor or character vector of values
- `levels`: character vector of factor levels
- `vmode`: one of the integer vmodes in `.rammode`

**Details**

Factors stored in unsigned vmodes `.vunsigned` have their first level represented as 0L instead of 1L.

**Value**

A vector of integer values representing the corresponding factor levels.
**ramattribs**

**Author(s)**

Jens Oehlschlägel

**See Also**

`factor`, `levels.ff`, `vmode`

**Examples**

```r
ram2ffcode(letters, letters, vmode="byte")
ram2ffcode(letters, letters, vmode="ubyte")
ram2ffcode(letters, letters, vmode="nibble")
message('note that ram2ffcode() does NOT warn that vmode="nibble" cannot store 26 levels')
```

---

**Description**

Functions `ramclass` and `ramattribs` return the respective virtual attributes, that determine which class (and attributes) an `ff` object receives when subscripted (or coerced) to `ram`.

**Usage**

```r
ramclass(x, ...)
## S3 method for class 'ff'
ramclass(x, ...)
## Default S3 method:
ramclass(x, ...)
ramattribs(x, ...)
## S3 method for class 'ff'
ramattribs(x, ...)
## Default S3 method:
ramattribs(x, ...)
```

**Arguments**

- `x`
- `...`

Further arguments (not used)

**Details**

`ramclass` and `ramattribs` provide a general mechanism to store atomic classes in `ff` objects, for example `factor` – see `levels.ff` – and `POSIXct`, see the example.
ramorder.default

Value

ramclass returns a character vector with classnames and ramattrs returns a list with names elements just like attributes. The vectors ramclass_excludes and ramattrs_excludes name those attributes, which are not exported from ff to ram objects when using as.ram.

Author(s)

Jens Oehlschlägel

See Also

ff, virtual, as.ram, levels.ff, attributes, DateTimeClasses

Examples

x <- ff(as.POSIXct(as.POSIXlt(Sys.time(), "GMT")), length=12)
x
ramclass(x)
ramattrs(x)
class(x[])
attributes(x[])
virtual(x)$ramattrs$tzone = NULL
attributes(x[])
rm(x); gc()

Description

Function ramorder will order the input vector in-place (without making a copy) and return the number of NAs found

Usage

## Default S3 method:
ramorder(x, i, has.na = TRUE, na.last = TRUE, decreasing = FALSE,
stable = TRUE, optimize = c("time", "memory"), VERBOSE = FALSE, ...)
## Default S3 method:
mergeorder(x, i, has.na = TRUE, na.last = TRUE, decreasing = FALSE, ...)
## Default S3 method:
radixorder(x, i, has.na = TRUE, na.last = TRUE, decreasing = FALSE, ...)
## Default S3 method:
keyorder(x, i, keyrange=range(x, na.rm=has.na), has.na = TRUE, na.last = TRUE,
downcreasing = FALSE, ...)
## Default S3 method:
shellorder(x, i, has.na = TRUE, na.last = TRUE, decreasing = FALSE, stabilize=FALSE, ...)
Arguments

- **x**: an atomic R vector
- **i**: a integer vector with a permutation of positions in x (you risk a crash if you violate this)
- **keyrange**: an integer vector with two values giving the smallest and largest possible value in x, note that you should give this explicitly for best performance, relying on the default needs one pass over the data to determine the range
- **has.na**: boolean scalar telling ramorder whether the vector might contain NAs. *Note* that you risk a crash if there are unexpected NAs with has.na=FALSE
- **na.last**: boolean scalar telling ramorder whether to order NAs last or first. *Note* that 'boolean' means that there is no third option NA as in `order`
- **decreasing**: boolean scalar telling ramorder whether to order increasing or decreasing
- **stable**: set to false if stable ordering is not needed (may enlarge the set of ordering methods considered)
- **optimize**: by default ramorder optimizes for 'time' which requires more RAM, set to 'memory' to minimize RAM requirements and sacrifice speed
- **VERBOSE**: cat some info about chosen method
- **stabilize**: Set to TRUE for stabilizing the result of shellorder (for equal keys the order values will be sorted, this only works if i=1:n) to minimize RAM requirements and sacrifice speed
- ... ignored

Details

Function `ramorder` is a front-end to a couple of single-threaded ordering algorithms that have been carefully implemented to be fast with and without NAs.

The default is a mergeorder algorithm without copying (Sedgewick 8.4) for integer and double data which requires 2x the RAM of its input vector (character or complex data are not supported). Mergeorder is fast, stable with a reliable runtime.

For integer data longer than a certain length we improve on mergeorder by using a faster LSD radixorder algorithm (Sedgewick 10.5) that uses 2x the RAM of its input vector plus 65536+1 integers.

For booleans, logicals, integers at or below the resolution of smallint and for factors below a certain number of levels we use a key-index order instead of mergeorder or radix order (note that R has a (slower) key-index order in `sort.list` available with confusingly named method='radix' but the standard `order` does not leverage it for factors (2-11.1). If you call `keyorder` directly, you should provide a known 'keyrange' directly to obtain the full speed.

Finally the user can request a order method that minimizes memory use at the price of longer computation time with optimize='memory' – currently a shellorder.

Value

integer scalar with the number of NAs. This is always 0 with has.na=FALSE
Note
This function is called for its side-effects and breaks the functional programming paradigm. Use with care.

i
x[i]

## Not run:
message("Note how the datatype influences sorting speed")
n <- 1e7
x <- sample(1:26, n, TRUE)

y <- as.double(x)
i <- 1:n
system.time(ramorder(y, i))

y <- as.integer(x)
i <- 1:n
system.time(ramorder(y, i))

y <- as.short(x)
i <- 1:n
system.time(ramorder(y, i))

y <- factor(letters)[x]
i <- 1:n
system.time(ramorder(y, i))

## End(Not run)
Description

Function ramsort will sort the input vector in-place (without making a copy) and return the number of NAs found.

Usage

```r
## Default S3 method:
ramsort(x, has.na = TRUE, na.last = TRUE, decreasing = FALSE
, optimize = c("time", "memory"), VERBOSE = FALSE, ...)
## Default S3 method:
mergesort(x, has.na = TRUE, na.last = TRUE, decreasing = FALSE, ...)
## Default S3 method:
radixsort(x, has.na = TRUE, na.last = TRUE, decreasing = FALSE, ...)
## Default S3 method:
keysort(x, keyrange=range(x, na.rm=has.na), has.na = TRUE
, na.last = TRUE, decreasing = FALSE, ...)
## Default S3 method:
shellsort(x, has.na = TRUE, na.last = TRUE, decreasing = FALSE, ...)
```

Arguments

- `x`: an atomic R vector
- `keyrange`: an integer vector with two values giving the smallest and largest possible value in `x`, note that you should give this explicitly for best performance, relying on the default needs one pass over the data to determine the range
- `has.na`: boolean scalar telling ramsort whether the vector might contain NAs. *Note* that you risk a crash if there are unexpected NAs with `has.na=FALSE`
- `na.last`: boolean scalar telling ramsort whether to sort NAs last or first. *Note* that 'boolean' means that there is no third option NA as in `sort`
- `decreasing`: boolean scalar telling ramsort whether to sort increasing or decreasing
- `optimize`: by default ramsort optimizes for 'time' which requires more RAM, set to 'memory' to minimize RAM requirements and sacrifice speed
- `VERBOSE`: cat some info about chosen method
- `...`: ignored

Details

Function ramsort is a front-end to a couple of single-threaded sorting algorithms that have been carefully implemented to be fast with and without NAs. The default is a mergesort algorithm without copying (Sedgewick 8.4) for integer and double data.
which requires 2x the RAM of its input vector (character or complex data are not supported). Mergesort is fast, stable with a reliable runtime.

For integer data longer than a certain length we improve on mergesort by using a faster LSD radix-sort algorithm (Sedgewick 10.5) that uses 2x the RAM of its input vector plus 65536+1 integers. For booleans, logicals, integers at or below the resolution of smallint and for factors below a certain number of levels we use a key-index sort instead of mergesort or radix sort (note that R has a (slower) key-index sort in sort.list available with confusingly named method='radix' but the standard sort does not leverage it for factors (2-11.1). If you call keysort directly, you should provide a known 'keyrange' directly to obtain the full speed.

Finally the user can request a sort method that minimizes memory use at the price of longer computation time with optimize='memory' – currently a shellsort.

Value

integer scalar with the number of NAs. This is always 0 with has.na=FALSE

Note

This function is called for its side-effects and breaks the functional programming paradigm. Use with care.

---

read.table.ffdf  Importing csv files into ff data.frames

Description

Function `read.table.ffdf` reads separated flat files into `ffdf` objects, very much like (and using) `read.table`. It can also work with any convenience wrappers like `read.csv` and provides its own convenience wrapper (e.g. `read.csv.ffdf`) for R’s usual wrappers.

Usage

```r
read.table.ffdf(
  x = NULL,
  file, fileEncoding = "",
  nrows = -1, first.rows = NULL, next.rows = NULL,
  levels = NULL, appendLevels = TRUE,
  FUN = "read.table", ...,
  transFUN = NULL,
  asffdf_args = list(),
  BATCHBYTES = getOption("ffbatchbytes"),
  VERBOSE = FALSE
)
```

```r
read.csv.ffdf(...) 
read.csv2.ffdf(...) 
read.delim.ffdf(...) 
read.delim2.ffdf(...) 
```

Arguments

- `x` NULL or an optional `ffdf` object to which the read records are appended. If this is provided, it defines crucial features that are otherwise determined during the ’first’ chunk of reading: `vmodes`, `colnames`, `colClasses`, sequence of predefined `levels`.

- `file` the name of the file which the data are to be read from. Each row of the table appears as one line of the file. If it does not contain an `absolute` path, the file name is `relative` to the current working directory, `getwd()`. Tilde-expansion is performed where supported.
read.table.ffdf

Alternatively, file can be a readable text-mode connection (which will be opened for reading if necessary, and if so closed (and hence destroyed) at the end of the function call).

fileEncoding character string: if non-empty declares the encoding used on a file (not a connection) so the character data can be re-encoded. See file.

nrows integer: the maximum number of rows to read in (includes first.rows in case a 'first' chunk is read) Negative and other invalid values are ignored.

first.rows integer: number of rows to be read in the first chunk, see details. Default is the value given at next.rows or 1e3 otherwise. Ignored if x is given.

next.rows integer: number of rows to be read in further chunks, see details. By default calculated as BATCHBYTES %/% sum(.rambytes[vmode(x)])

levels NULL or an optional list, each element named with col.names of factor columns specifies the levels Ignored if x is given.

appendLevels logical. A vector of permissions to expand levels for factor columns. Recycled as necessary, or if the logical vector is named, unspecified values are taken to be TRUE. Ignored during processing of the 'first' chunk

FUN character: name of a function that is called for reading each chunk, see read.table, read.csv, etc.

... further arguments, passed to FUN in read.table.ffdf, or passed to read.table.ffdf in the convenience wrappers

transFUN NULL or a function that is called on each data.frame chunk after reading with FUN and before further processing (for filtering, transformations etc.)

asffdf_args further arguments passed to as.ffdf when converting the data.frame of the first chunk to ffdf. Ignored if x is given.

BATCHBYTES integer: bytes allowed for the size of the data.frame storing the result of reading one chunk. Default getOption("ffbatchbytes").

VERBOSE logical: TRUE to verbose timings for each processed chunk (default FALSE)

Details

read.table.ffdf has been designed to read very large (many rows) separated flatfiles in row-chunks and store the result in a ffdf object on disk, but quickly accessible via ff techniques.

The first chunk is read with a default of 1000 rows, for subsequent chunks the number of rows is calculated to not require more RAM than getOption("ffbatchbytes"). The following could be indications to change the parameter first.rows:

1. set first.rows=-1 to read the complete file in one go (requires enough RAM)
2. set first.rows to a smaller number if the pre-allocation of RAM for the first chunk with parameter nrows in read.table is too large, i.e. with many columns on machine with little RAM.
3. set first.rows to a larger number if you expect better factor level ordering (factor levels are sorted in the first chunk, but not at subsequent chunks, however, factor level ordering can be fixed later, see below).
By default the \texttt{ffdf} object is created on the fly at the end of reading the 'first' chunk, see argument \texttt{first.rows}. The creation of the \texttt{ffdf} object is done via \texttt{as.ffdf} and can be finetuned by passing argument \texttt{asffdf.args}. Even more control is possible by passing in a \texttt{ffdf} object as argument \texttt{x} to which the read records are appended. \texttt{read.table.ffdf} has been designed to behave as much like \texttt{read.table} as possible. However, note the following differences:

1. Arguments 'colClasses' and 'col.names' are now enforced also during 'next.rows' chunks. For example giving \texttt{colClasses=NA} will force that no colClasses are derived from the \texttt{first.rows} respective from the \texttt{ffdf} object in parameter \texttt{x}.
2. colClass 'ordered' is allowed and will create an \texttt{ordered} factor
3. character vector are not supported, character data must be read as one of the following col-Classes: 'Date', 'POSIXct', 'factor, 'ordered'. By default character columns are read as factors. Accordingly arguments 'as.is' and 'stringsAsFactors' are not allowed.
4. the sequence of \texttt{levels.ff} from chunked reading can depend on chunk size: by default new levels found on a chunk are appended to the levels found in previous chunks, no attempt is made to sort and recode the levels during chunked processing. levels can be sorted and recoded most efficiently \texttt{after} all records have been read using \texttt{sortLevels}.
5. the default for argument 'comment.char' is "" even for those \texttt{FUN} that have a different default. However, explicit specification of 'comment.char' will have priority.

\textbf{Value}

An \texttt{ffdf} object. If created during the 'first' chunk pass, it will have one physical component per virtual column.

\textbf{Note}

Note that using the 'skip' argument still requires to read the file from beginning in order to count the lines to be skipped. If you first read part of the file in order to understand its structure and then want to continue, a more efficient solution that using 'skip' is opening a \texttt{file connection} and pass that to argument 'file'. \texttt{read.table.ffdf} does the same in order to skip efficiently over previously read chunks.

      , dat="single"
    )
  )
)
Simpe low-level interface for reading and writing vectors from ff files.

Description

ReadWrite.ff
Usage

read.ff(x, i, n)
write.ff(x, i, value, add = FALSE)
readwrite.ff(x, i, value, add = FALSE)

Arguments

x an ff object
i a start position in the ff file
n number of elements to read
value vector of elements to write
add TRUE if the values should rather increment than overwrite at the target positions

Details

readwrite.ff combines the effects of read.ff and write.ff in a single operation: it retrieves the old values starting from position i before changing them. getset.ff will maintain na.count.

Value

read.ff returns a vector of values, write.ff returns the 'changed' ff object (like all assignment functions do) and readwrite.ff returns the values at the target position. More precisely readwrite.ff(x,i,value,add=FALSE) returns the old values at the position i while readwrite.ff(x,i,value,add=TRUE) returns the incremented values of x.

Note

read.ff, write.ff and readwrite.ff are low level functions that do not support ramclass and ramattribs and thus will not give the expected result with factor and POSIXct

Author(s)

Jens Oehlschlägel

See Also

getset.ff for low-level scalar access and [.ff for high-level access

Examples

x <- ff(0, length=12)
read.ff(x, 3, 6)
write.ff(x, 3, rep(1, 6))
x
write.ff(x, 3, rep(1, 6), add=TRUE)
x
readwrite.ff(x, 3, rep(1, 6), add=TRUE)
x
readwrite.ff(x, 3, rep(1, 6))
x
rm(x); gc()
Description
Some tests verifying the correctness of the sorting routines

Usage
regtest.fforder(n = 100)

Arguments
n size of vector to be sorted

Details
stops in case of an error

Value
Invisible()

Author(s)
Jens Oehlschlägel

See Also
ramsort

Examples
regtest.fforder()

## End(Not run)
Description

Function `repnam` replicates its argument to the desired length, either by simply replicating or - if it has names - by replicating the default and matching the argument by its names.

Usage

`repnam(argument, names = NULL, len=length(names), default = list(NULL))`

Arguments

- **argument**: a named or non-named vector or list to be replicated
- **names**: NULL or a character vector of names to which the argument names are matched
- **len**: the desired length (required if names is not given)
- **default**: the desired default which is replicated in case names are used (the default `list(NULL)` is suitable for a list argument)

Value

an object like argument or default having length `len`

Note

This is for internal use, e.g. to handle argument `colClasses` in `read.table.ffdf`

Author(s)

Jens Oehlschlägel

See Also

`rep`, `vector`, `repfromto`

Examples

```
message("a list example")
repnam(list(y=c(1,2), z=3), letters)
repnam(list(c(1,2), 3), letters)

message("a vector example")
repnam(c(y=1, z=3), letters, default=NA)
repnam(c(1, 3), letters, default=NA)
```
sortLevels  

Factor level manipulation

Description

appendLevels combines levels without sorting such that levels of the first argument will not require re-coding.
recodeLevels is a generic for recoding a factor to a desired set of levels - also has a method for large ff objects
sortLevels is a generic for level sorting and recoding of single factors or of all factors of a ffdf dataframe.

Usage

appendLevels(...)  
recodeLevels(x, lev)
## S3 method for class 'factor'
recodeLevels(x, lev)
## S3 method for class 'ff'
recodeLevels(x, lev)
sortLevels(x)
## S3 method for class 'factor'
sortLevels(x)
## S3 method for class 'ff'
sortLevels(x)
## S3 method for class 'ffdf'
sortLevels(x)

Arguments

... character vector of levels or is.factor objects from which the level attribute is taken
x a factor or ff factor or a ffdf dataframe (sortLevels only)
lev a character vector of levels

Details

When reading a long file with categorical columns the final set of factor levels is only known once the complete file has been read. When a file is so large that we read it in chunks, the new levels need to be added incrementally. bind.data.frame sorts combined levels, which requires recoding. For ff factors this would require recoding of all previous chunks at the next chunk - potentially on disk, which is too expensive. Therefore read.table.ffdf will simply appendLevels without sorting, and the recodeLevels and sortLevels generics provide a convenient means for sorting and recoding levels after all chunks have been read.
appendLevels returns a vector of combined levels, recodeLevels and sortLevels return the input object with changed levels. Do read the note!

Note

You need to re-assign the return value not only for ram- but also for ff-objects. Remember ff’s hybrid copying semantics: LimWarn. If you forget to re-assign the returned object, you will end up with ff objects that have their integer codes re-coded to the new levels but still carry the old levels as a virtual attribute.

splitPathFile

### Analyze pathfile-strings

**Description**

`splitPathFile` splits a vector of pathfile-strings into path- and file-components without loss of information. `unsplitPathFile` restores the original pathfile-string vector. `standardPathFile` standardizes a vector of pathfile-strings: backslashes are replaced by slashes, except for the first two leading backslashes indicating a network share. `tempPathFile` returns - similar to `tempfile` - a vector of filenames given path(s) and file-prefix(es) and an optional extension. `fftempfile` returns - similar to `tempPathFile` - a vector of filenames following a vector of pathfile patterns that are interpreted in a ff-specific way.
splitPathFile

Usage

   splitPathFile(x)
   unsplitPathFile(splitted)
   standardPathFile(x)
   tempPathFile(splitted=NULL, path=splitted$path, prefix=splitted$file, extension=NULL)
   fftempfile(x)

Arguments

   x              a character vector of pathfile strings
   splitted       a return value from splitPathFile
   path           a character vector of path components
   prefix         a character vector of file components
   extension      optional extension like "csv" (or NULL)

Details

dirname and basename remove trailing file separators and therefore cannot distinguish pathfile string that contains ONLY a path from a pathfile string that contains a path AND file. Therefore file.path(dirname(pathfile),basename(pathfile)) cannot always restore the original pathfile string.

splitPathFile decomposes each pathfile string into three parts: a path BEFORE the last file separator, the file separator, the filename component AFTER the last file separator. If there is no file separator in the string, splitPathFile tries to guess whether the string is a path or a file component: ".", ".", and "~" are recognized as path components. No tilde expansion is done, see path.expand. Backslashes are converted to the current .Platform$file.sep using splitPathFile except for the first two leading backslashes indicating a network share.

unsplitPathFile restores the original pathfile-string vector up to translated backslashes.

tempPathFile internally uses tempfile to create its filenames, if an extension is given it repeats filename creation until none of them corresponds to an existing file.

fftempfile takes a path-prefix pattern as input, splits it, will replace an empty path by getOption("fftempdir") and will use getOption("ffextension") as extension.

Value

A list with components

   path      a character vector of path components
   fsep      a character vector of file separators or ""
   file      a character vector of file components

Note

There is no guarantee that the path and file components contain valid path- or file-names. Like basename, splitPathFile can return ".", ".", or even ""; however, all these make sense as a prefix in tempPathFile.

  d <- dirname(pathfile)
  b <- basename(pathfile)
})
```

```r
len <- c(1,10,100,1000)
timings <- matrix(0, 2, length(len), dimnames=list(c("dir.base.name", "splitPathFile"), len))
for (j in seq(along=len)){
  l <- len[j]
  r <- 10000 / l
  x <- rep("\\a/b/", l)
timings[1,j] <- system.time(for (i in 1:r){
    d <- dirname(x)
    b <- basename(x)
  })
```
swap

Reading and writing in one operation (high-level)

Description

The generic \texttt{swap} combines \texttt{x[i]} and \texttt{x[i] <-value} in a single operation.

Usage

\begin{verbatim}
swap(x, value, ...)  
## S3 method for class 'ff'
swap(x, value, i, add = FALSE, pack = FALSE, ...)  
## S3 method for class 'ff_array'
swap(x, value, ..., bydim = NULL, drop = getOption("ffdrop"), add = FALSE, pack = FALSE)  
## Default S3 method:
swap(x, value, ..., add = FALSE)
\end{verbatim}

Arguments

- \texttt{x}: \texttt{ff} or \texttt{ram} object
- \texttt{value}: the new values to write, possibly recycled, see \texttt{\texttt{\[.ff}}
- \texttt{i}: index information, see \texttt{\texttt{\[.ff}}
- \texttt{...}: missing OR up to \texttt{length(dim(x))} index expressions OR (ff only) \texttt{hi} objects
- \texttt{drop}: logical scalar indicating whether array dimensions shall be dropped
- \texttt{bydim}: how to interpret vector to array data, see \texttt{\texttt{\[.ff}}
- \texttt{add}: TRUE if the values should rather increment than overwrite at the target positions, see \texttt{readwrite.ff}
- \texttt{pack}: FALSE to prevent rle-packing in hybrid index preprocessing, see \texttt{as.hi}

Details

\begin{verbatim}
y <- swap(x, value, i, add=FALSE, ...)
\end{verbatim}

is a shorter and more efficient version of

\begin{verbatim}
y <- x[i, add=FALSE, ...]  
x[i, add=FALSE, ...] <- value
\end{verbatim}
and

\[
\begin{align*}
  y &\leftarrow \text{swap}(x, \text{value}, i, \text{add=} \text{TRUE}, \ldots) \\
  \text{is a shorter and more efficient version of} \\
  y &\leftarrow x[i, \text{add=} \text{TRUE}, \ldots] \\
  y &\leftarrow y + \text{value} \\
  x[i, \text{add=} \text{FALSE}, \ldots] &\leftarrow y
\end{align*}
\]

**Value**

Values at the target positions. More precisely `\text{swap}(x, \text{value}, i, \text{add=} \text{FALSE})` returns the old values at the position `i` while `\text{swap}(x, \text{value}, i, \text{add=} \text{TRUE})` returns the incremented values of `x`.

**Note**

Note that `\text{swap.default}` changes the object in its parent frame and thus violates R’s usual functional programming logic. When using `\text{add=} \text{TRUE}`, duplicated index positions should be avoided, because `ff` and `ram` objects behave differently:

\[
\begin{align*}
  \text{swap.ff}(x, 1, c(3,3), \text{add=} \text{TRUE}) &\quad \# \text{will increment x at position 3 TWICE by 1, while} \\
  \text{swap.default}(x, 1, c(3,3), \text{add=} \text{TRUE}) &\quad \# \text{will increment x at position 3 just ONCE by 1}
\end{align*}
\]

**Author(s)**

Jens Oehlschlägel

**See Also**

`.ff.add`, `readwrite.ff`, `getset.ff`, `LimWarn`

**Examples**

\[
\begin{align*}
  x &\leftarrow \text{ff}(\text{"a"}, \text{levels=} \text{letters}, \text{length=} 52) \\
  y &\leftarrow \text{swap}(x, \text{"b"}, \text{sample}(\text{length}(x), 26)) \\
  x \\
  y \\
  \text{rm}(x,y); \text{gc()}
\end{align*}
\]
symmetric

Test for symmetric structure

Description
Check if an object is inherently symmetric (its structure, not its data)

Usage

```r
symmetric(x, ...)  
## S3 method for class 'ff'
symmetric(x, ...)  
## Default S3 method:
symmetric(x, ...)  
## S3 method for class 'dist'
symmetric(x, ...)
```

Arguments

- `x` an ff or ram object
- `...` further arguments (not used)

Details

ff matrices can be declared symmetric at creation time. Compatibility function `symmetric.default` returns FALSE, `symmetric.dist` returns TRUE.

Value

TRUE or FALSE

Author(s)

Jens Oehlschlägel

`symmetric`, `ff`, `dist`, `isSymmetric`

Examples

```r
symmetric(matrix(1:16, 4, 4))
symmetric(dist(rnorm(1:4)))
```
symmIndex2vectorIndex  Array: make vector positions from symmetric array index

Description
make vector positions from (non-symmetric) array index respecting ‘dim’ and ‘fixdiag’

Usage
symmIndex2vectorIndex(x, dim, fixdiag = NULL)

Arguments
x  
a matrix[,1:2] with matrix subscripts

dim  
the dimensions of the symmetric matrix

fixdiag  
NULL assumes free diagonal, any value assumes fixed diagonal

Details
With ‘fixdiag = NULL’

Value
a vector of indices in seq_len(prod(dim(x)))

Author(s)
Jens Oehlschlägel

See Also
arrayIndex2vectorIndex

Examples
symmIndex2vectorIndex(rbind(
  c(1,1),
  c(1,10),
  c(10,1),
  c(10,10)
), dim=c(10,10))
symmIndex2vectorIndex(rbind(
  c(1,1),
  c(1,10),
  c(10,1),
  c(10,10)
), dim=c(10,10), fixdiag=1)
Description

With `unclass<-` you can circumvent class dispatch on the assignment operator.

Usage

```r
unclass(x) <- value
```

Arguments

- `x`: some object
- `value`: the value to be assigned

Value

the modified object

Author(s)

Jens Oehlschlägel

See Also

`unclass`, `undim`

Examples

```r
x <- factor(letters)
unclass(x)[1:3] <- 1L
x
```

---

Description

`undim` returns its input with the dim attribute removed

Usage

```r
undim(x)
```
Arguments

x an object

Value

x without dim attribute

Author(s)

Jens Oehlschlägel

See Also

unclass<-, unclass, unname, dim

Examples

x <- matrix(1:12, 3)
xundim(x)

Description

Non-documented internal utilities that might change

Usage

unsort(x, ix)
unsort.hi(x, index)
unsort.ahi(x, index, ixre = any(sapply(index, function(i) {
if (is.null(i$ix)) {
if (i$re) TRUE else FALSE
} else {
TRUE
}
})
)), ix = lapply(index, function(i) {
if (is.null(i$ix)) {
if (i$re)
orig <- rev(seq_len(poslength(i)))
else orig <- seq_len(poslength(i))
} else {
orig <- i$ix
}
})
update.ff

orig
})
subscript2integer(x, maxindex = NULL, names = NULL)

Arguments

- `x`
- `ix`
- `ixre`
- `index`
- `maxindex`
- `names`

Details

These are utility functions for restoring original order after sorting. For now we 'mimic' the intuitive
but wrong argument order of match() which should rather have the 'table' argument as its first
argument, then one could properly method-dispatch on the type of table. xx We might change to
proper 'unsort' generic, but then we have to change argument order.

Value

undefined

Author(s)

Jens Oehlschlägel

See Also

`hi`, `as.hi`

update.ff

Update ff content from another object

Description

update copies updates one ff object with the content of another object.

Usage

```r
## S3 method for class 'ff'
update(object, from, delete = FALSE, bydim = NULL, fromdim = NULL,
       BATCHSIZE = .Machine$integer.max, BATCHBYTES = getOption("ffbatchbytes")
       , VERBOSE = FALSE, ...)
## S3 method for class 'ffdf'
update(object, from, ...)
```
Arguments

object an ff object to which to update
from an object from which to update
delete NA for quick update with file-exchange, TRUE for quick update with deleting the 'from' object after the update, can speed up updating significantly
bydim how to interpret the content of the object, see \texttt{ff}
fromdim how to interpret the content of the 'from' object, see \texttt{ff}
BATCHSIZE BATCHSIZE
BATCHBYTES BATCHBYTES
VERBOSE VERBOSE
... further arguments

Details

If the source object \texttt{is.ff} and not delete=FALSE then instead of slow copying we - if possible - try to swap and rename the files behind the ff objects. Quick update requires that the two ff objects are \texttt{vectorCompatible}, that both don’t use \texttt{vw}, that they have identical \texttt{maxlength} and identical \texttt{levels.ff}.

Value

An ff object like the input 'object' updated with the content of the 'from' object.

Note

You don’t have a guarantee that with delete=TRUE the 'from' object gets deleted or with delete=NA the 'from' objects carries the content of 'object'. Such expectations only turn true if really a quick update was possible.

Author(s)

Jens Oehlschlägel

See Also

\texttt{ff, clone, ffvecapply, vectorCompatible, filename}

Examples

```r
x <- ff(1:100)
y <- ff(-(1:100))
message("You should make it a habit to re-assign the return value of update although this is not needed currently."")
x <- update(x, from=y)
x
y
x[] <- 1:100
```
vecprint

Print beginning and end of big vector

Description

Print beginning and end of big vector

Usage

vecprint(x, maxlen = 16, digits = getOption("digits"))

## S3 method for class 'vecprint'
print(x, quote = FALSE, ...)

Arguments

x a vector
maxlen max number of elements for printing
digits see format
quote see print
... see print

Value

a list of class 'vecprint' with components

subscript a list with two vectors of subscripts: vector begin and vector end
example the extracted example vector as.character including seperator
sep the row seperator ":"
Author(s)

Jens Oehlschlägel

See Also

matprint

Examples

vecprint(10000:1)

---

vector.vmode (Create vector of virtual mode)

Description

vector.vmode creates a vector of a given vmode and length

Usage

vector.vmode(vmode = "logical", length = 0)
boolean(length = 0)
quad(length = 0)
nibble(length = 0)
byte(length = 0)
ubyte(length = 0)
short(length = 0)
ushort(length = 0)

Arguments

vmode virtual mode
length desired length

Details

Function vector.vmode creates the vector in one of the usual storage.modes (see .rammode) but flags them with an additional attribute 'vmode' if necessary. The creators can also be used directly:

boolean 1 bit logical without NA
logical 2 bit logical with NA
quad 2 bit unsigned integer without NA
nibble 4 bit unsigned integer without NA
byte 8 bit signed integer with NA
ubyte 8 bit unsigned integer without NA
short 16 bit signed integer with NA
ushort 16 bit unsigned integer without NA
vector2array

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer</td>
<td>32 bit signed integer with NA</td>
</tr>
<tr>
<td>single</td>
<td>32 bit float</td>
</tr>
<tr>
<td>double</td>
<td>64 bit float</td>
</tr>
<tr>
<td>complex</td>
<td>2x64 bit float</td>
</tr>
<tr>
<td>raw</td>
<td>8 bit unsigned char</td>
</tr>
<tr>
<td>character</td>
<td>character</td>
</tr>
</tbody>
</table>

Value

a vector of the desired vmode initialized with 0

Author(s)

Jens Oehlschlägel

See Also

as.vmode, vector

Examples

vector.vmode("byte",12)
vector.vmode("double",12)
byte(12)
double(12)

description

makes array from vector respecting 'dim' and 'dimorder'

Usage

vector2array(x, dim, dimorder = NULL)

Arguments

x an input vector, recycled if needed
dim dim
dimorder dimorder
vectorIndex2arrayIndex

Details

FILLS vector into array of dim where fastest rotating is dim[dimorder[1]], next is dim[dimorder[2]] and so forth. This is a generalization of converting vector to matrix(, byrow=TRUE). NOTE that the result is a ram array always stored in STANDARD dimorder !!! In this usage we sometimes term the dimorder 'bydim' because it does not change the physical layout of the result, rather bydim refers to the dimorder in which to interpret the vector (not the result). In ff, update and clone we have 'bydim' to contrast it from 'dimorder', the latter describing the layout of the file.

Value

a suitable array

Author(s)

Jens Oehlschlägel

See Also

array2vector, vectorIndex2arrayIndex

Examples

vector2array(1:12, dim=c(3, 4)) # matrix(1:12, 3, 4)
vector2array(1:12, dim=c(3, 4), dimorder=2:1) # matrix(1:12, 3, 4, byrow=TRUE)

vectorIndex2arrayIndex

Description

make array from index vector positions respecting ‘dim’ and ‘dimorder’

Usage

vectorIndex2arrayIndex(x, dim = NULL, dimorder = NULL, vw = NULL)

Arguments

  x a vector of indices in seq_len(prod(dim))
  dim NULL or dim
  dimorder NULL or dimorder
  vw NULL or integer matrix[2,m], see details
Details

The fastest rotating dimension is dim[dimorder[1]], then dim[dimorder[2]], and so forth. The parameters ‘x’ and ‘dim’ may refer to a subarray of a larger array, in this case, the array indices ‘x’ are interpreted as ‘vw[1,] + x’ within the larger array ‘vw[1,] + x + vw[2,]’.

Value

an n by m matrix with n m-dimensional array indices

Author(s)

Jens Oehlschlägel

See Also

vector2array, arrayIndex2vectorIndex, symmIndex2vectorIndex

Examples

matrix(1:12, 3, 4)
vectorIndex2arrayIndex(1:12, dim=3:4)
vectorIndex2arrayIndex(1:12, dim=3:4, dimorder=2:1)
matrix(1:30, 5, 6)
vectorIndex2arrayIndex(c(6L, 7L, 8L, 11L, 12L, 13L, 16L, 17L, 18L, 21L, 22L, 23L),
vw=rbind(c(0,1), c(3,4), c(2,1)))
vectorIndex2arrayIndex(c(2L, 8L, 14L, 3L, 9L, 15L, 4L, 10L, 16L, 5L, 11L, 17L),
vw=rbind(c(0,1), c(3,4), c(2,1)), dimorder=2:1)

---

### vmode

**Virtual storage mode**

**Description**

Function vmode returns virtual storage modes of `ram` or `ff` objects, the generic `vmode<-` sets the vmode of ram objects (vmode of ff objects cannot be changed).

**Usage**

vmode(x, ...)
vmode(x) <- value
## Default S3 method:
vmode(x, ...)
## S3 method for class 'ff'
vmode(x, ...)
## Default S3 replacement method:
vmode(x) <- value
## S3 replacement method for class 'ff'

```r
vmode(x) <- value
regtest.vmode()
```

### Arguments

- `x` any object
- `value` a vmode from `.vmode`
- `...` The ... don’t have a function yet, they are only defined to keep the generic flexible.

### Details

`vmode` is generic with default and ff methods. The following meta data vectors can be queried by `.vmode` or `.ffmode`:

- `.vmode` virtual mode
- `.vunsigned` TRUE if unsigned vmode
- `.vvalues` number of possible values (incl. NA)
- `.vimplemented` TRUE if this vmode is available in ff (initialized `.onLoad` and stored in `globalenv`)
- `.rammode` storage mode of this vmode
- `.ffmode` integer used to code the vmode in C-code
- `.vvalues` number of possible integers incl. NA in this vmode (or NA for other vmodes)
- `.vmin` min integer in this vmode (or NA for other vmodes)
- `.vmax` max integer in this vmode (or NA for other vmodes)
- `.vNA` NA or 0 if no NA for this vmode
- `.rambytes` bytes needed in ram
- `.ffbytes` bytes needed by ff on disk
- `.vcoerceable` list of vectors with those vmodes that can absorb this vmode

The following functions relate to `vmode`:

- `vector.vmode` creating (ram) vector of some vmode
- `as.vmode` generic for coercing to some vmode (dropping other attributes)
- `vmode<-` generic for coercing to some vmode (keeping other attributes)
- `maxffmode` determine lowest `.ffmode` that can absorb all input vmodes without information loss

Some of those call the vmode-specific functions:

<table>
<thead>
<tr>
<th>creation</th>
<th>coercion</th>
<th>vmode description</th>
</tr>
</thead>
<tbody>
<tr>
<td>boolean</td>
<td>as.boolean</td>
<td>1 bit logical without NA</td>
</tr>
<tr>
<td>logical</td>
<td>as.logical</td>
<td>2 bit logical with NA</td>
</tr>
<tr>
<td>quad</td>
<td>as.quad</td>
<td>2 bit unsigned integer without NA</td>
</tr>
<tr>
<td>nibble</td>
<td>as.nibble</td>
<td>4 bit unsigned integer without NA</td>
</tr>
<tr>
<td>byte</td>
<td>as.byte</td>
<td>8 bit signed integer with NA</td>
</tr>
<tr>
<td>ubyte</td>
<td>as.ubyte</td>
<td>8 bit unsigned integer without NA</td>
</tr>
</tbody>
</table>
short as.short 16 bit signed integer with NA
ushort as.ushort 16 bit unsigned integer without NA
integer as.integer 32 bit signed integer with NA
single as.single 32 bit float
double as.double 64 bit float
complex as.complex 2x64 bit float
raw as.raw 8 bit unsigned char
character as.character character

Value
vmode returns a character scalar from .vmode or "NULL" for NULL
rambytes returns a vector of byte counts required by each of the vmodes

Note
regtest.vmode checks correctness of some vmode features

Author(s)
Jens Oehlschlägel

.vcoerceable["ubyte"]

---

vmode.ffdf  Virtual storage mode of ffdf

Description
Function vmode returns the virtual storage mode of each ffdf column

Usage
## S3 method for class 'ffdf'
vmode(x, ...)

---
Arguments

- `x` (ffdf)
- `...` (ignored)

Value

A character vector with one element for each column

Author(s)

Jens Oehlschlägel

See Also

`vmode`, `ffdf`

Examples

```r
vmode(as.ffdf(data.frame(a=as.double(1:26), b=letters, stringsAsFactors = TRUE)))
gc()
```

---

**vt**

*Virtual transpose*

Description

The `vt` generic does a matrix or array transpose by modifying *virtual* attributes rather than by physically copying matrix elements.

Usage

```r
vt(x, ...)
## S3 method for class 'ff'
vt(x, ...)
## Default S3 method:
vt(x, ...)
## S3 method for class 'ff'
t(x)
```

Arguments

- `x` (an ff or ram object)
- `...` (further arguments (not used))
Details

The `vt.ff` method does transpose through reversing `dim.ff` and `dimorder`. The `vt.default` method is a wrapper to the standard transpose `t`.

The `t.ff` method creates a transposed clone.
If `x` has a virtual window `vw` defined, `vt.ff` returns an `ff` object with a transposed virtual window, the `t.ff` method return a transposed clone of the virtual window content only.

Value

an object that behaves like a transposed matrix

Author(s)

Jens Oehlschlägel

See Also

dim.ff, vw, virtual

Examples

```r
x <- ff(1:20, dim=c(4,5))
x
vt(x)
y <- t(x)
y
vw(x) <- cbind(c(1,3,0),c(1,4,0))
x
vt(x)
y <- t(x)
y
rm(x,y); gc()
```

Description

The virtual window `vw` function allows one to define a virtual window into an `ff_vector` or `ff_array`. The `ff` object will behave like a smaller array and it is mapped into the specified region of the complete array. This allows for example to execute recursive divide and conquer algorithms that work on parts of the full object, without the need to repeatedly create subfiles.
Usage

vw(x, ...) <- value
## S3 method for class 'ff'
vw(x, ...)
## Default S3 method:
vw(x, ...)
## S3 replacement method for class 'ff_vector'
vw(x, ...) <- value
## S3 replacement method for class 'ff_array'
vw(x, ...) <- value

Arguments

x an ff_vector or ff_array
...
value a vector or matrix with an Offset, Window and Rest component, see details and examples

Details

Each dimension of an ff array (or vector) is decomposed into three components, an invisible Offset, a visible Window and an invisible Rest. For each dimension the sum of the vw components must match the dimension (or length). For an ff_vector, vw is simply a vector[1:3], for an array is is a matrix[1:3, seq_along(dim(x))]. vw is a virtual attribute.

Value

NULL or a vw specification, see details

Author(s)

Jens Oehlschlägel

See Also

length.ff, dim.ff, virtual

Examples

x <- ff(1:26, names=letters)
y <- x
vw(x) <- c(0, 13, 13)
vw(y) <- c(13, 13, 0)
x
y
x[1] <- -1
y[1] <- -2
write.table.ffdf

vw(x) <- NULL
x[]

z <- ff(1:24, dim=c(4,6), dimnames=list(letters[1:4], LETTERS[1:6]))
z
vw(z) <- rbind(c(1,1), c(2,4), c(1,1))
z

rm(x,y,z); gc()

write.table.ffdf

Exporting csv files from ff data.frames

Description

Function write.table.ffdf writes a ffdf object to a separated flat file, very much like (and using) write.table. It can also work with any convenience wrappers like write.csv and provides its own convenience wrapper (e.g. write.csv.ffdf) for R’s usual wrappers.

Usage

write.table.ffdf(x = NULL, file, append = FALSE, nrows = -1, first.rows = NULL, next.rows = NULL, FUN = "write.table", ..., transFUN = NULL, BATCHBYTES = getOption("ffbatchbytes"), VERBOSE = FALSE)

write.csv.ffdf(...)
write.csv2.ffdf(...)
write.csv(...)
write.csv2(...)

Arguments

x a ffdf object which to export to the separated file
file either a character string naming a file or a connection open for writing. "" indicates output to the console.
append logical. Only relevant if file is a character string. If TRUE, the output is appended to the file. If FALSE, any existing file of the name is destroyed.
nrows integer: the maximum number of rows to write in (includes first.rows in case a 'first' chunk is read) Negative and other invalid values are ignored.
first.rows the number of rows to write with the first chunk (default: next.rows)
next.rows integer: number of rows to write in further chunks, see details. By default calculated as BATCHBYTES %/% sum(.rambytes[vmode(x)])
write.table.ffdf

FUN character: name of a function that is called for writing each chunk, see `write.table`, `write.csv`, etc.

... further arguments, passed to FUN in `write.table.ffdf`, or passed to `write.table.ffdf` in the convenience wrappers

transFUN NULL or a function that is called on each data.frame chunk before writing with FUN (for filtering, transformations etc.)

BATCHBYTES integer: bytes allowed for the size of the data.frame storing the result of reading one chunk. Default `getOption("ffbatchbytes")`.

VERBOSE logical: TRUE to verbose timings for each processed chunk (default FALSE)

Details

`write.table.ffdf` has been designed to export very large `ffdf` objects to separated flatfiles in chunks. The first chunk is potentially written with col.names. Further chunks are appended.

`write.table.ffdf` has been designed to behave as much like `write.table` as possible. However, note the following differences:

1. by default `row.names` are only written if the `ffdf` has row.names.

Value

invisible

Note

`write.csv` and `write.csv2` have been fixed in order to suppress col.names if append=TRUE is passed. Note also that `write.table.ffdf` passes col.names=FALSE for all chunks following the first chunk - but not so for FUN="write.csv" and FUN="write.csv2".

Author(s)

Jens Oehlschlägel, Christophe Dutang
