Package ‘glmnetr’

March 4, 2024

Title Nested Cross Validation for the Relaxed Lasso and Other Machine Learning Models

Version 0.4-3

Date 2024-03-01

Depends R (>= 3.4.0)

Suggests R.rsp

VignetteBuilder R.rsp

Imports glmnet, survival, Matrix, xgboost, smoof, mlrMBO, ParamHelpers, randomForestSRC, rpart, torch

ByteCompile Yes

Author Walter K Kremers [aut, cre] (<https://orcid.org/0000-0001-5714-3473>), Nicholas B Larson [ctb]

Maintainer Walter K Kremers <kremers.walter@mayo.edu>

Description Cross validation informed Relaxed LASSO, Artificial Neural Network (ANN), gradient boosting machine (‘xgboost’), Random Forest (‘RandomForestSRC’), Recursive Partitioning (‘RPART’) or step wise regression models are fit. Nested cross validation (or analogous for the random forest) is used to estimate and compare performances between these models. For some datasets, for example when the design matrix is not of full rank, ‘glmnet’ may have very long run times when fitting the relaxed lasso model, from our experience when fitting Cox models on data with many predictors and many patients, making it difficult to get solutions from either glmnet() or cv.glmnet(). This may be remedied with the ‘path=TRUE’ options when calling glmnet() and cv.glmnet(). Within the glmnetr package the approach of path=TRUE is taken by default. When fitting not a relaxed lasso model but an elastic-net model, then the R-packages ‘nestedcv’ <https://cran.r-project.org/package=nestedcv>, ‘glmnetSE’ <https://cran.r-project.org/package=glmnetSE> or others may provide greater functionality when performing a nested CV. As with the ‘glmnet’ package, this package passes most relevant output to the output object and tabular and graphical summaries can be generated using the summary and plot functions. Use of the ‘glmnetr’ has many similarities to the ‘glmnet’ package and it is recommended that the user of ‘glmnetr’ also become familiar with the ‘glmnet’ package <https://cran.r-project.org/package=glmnet>, with the ```An Introduction to 'glmnet'``` and ```The Relaxed Lasso``` being especially helpful in this regard.

Identify model based upon AIC criteria from a stepreg() output

Description

Identify model based upon AIC criteria from a stepreg() output

Usage

aicreg(
  xs,
  start,
  y_,
  event,
  steps_n = steps_n,
  family = family,
  object = NULL,
  track = 0
)

Arguments

xs  predictor input - an n by p matrix, where n (rows) is sample size, and p (columns) the number of predictors. Must be in matrix form for complete data, no NA’s, no Inf’s, etc., and not a data frame.

start  start time, Cox model only - class numeric of length same as number of patients (n)

y_  output vector: time, or stop time for Cox model, y_ 0 or 1 for binomial (logistic), numeric for gaussian. Must be a vector of length same as number of sample size.
event indicator, 1 for event, 0 for census, Cox model only. Must be a numeric vector of length same as sample size.
steps_n maximum number of steps done in stepwise regression fitting
family model family, "cox", "binomial" or "gaussian"
object A stepreg() output. If NULL it will be derived.
track Indicate whether or not to update progress in the console. Default of 0 suppresses these updates. The option of 1 provides these updates. In fitting clinical data with non full rank design matrix we have found some R-packages to take a very long time or possibly get caught in infinite loops. Therefore we allow the user to track the package and judge whether things are moving forward or if the process should be stopped.

Value
The identified model in form of a glm() or coxph() output object, with an entry of the stepreg() output object.

Examples
set.seed(18306296)
sim.data=glmnetr.simdata(nrows=100, ncols=100, beta=c(0,1,1))
# this gives a more intersting case but takes longer to run
xs=sim.data$x
# this will work numerically
xs=sim.data$x[,c(2,3,50:55)]
y_=sim.data$y
event=sim.data$event
cox.aic.fit = aicreg(xs, NULL, y_, event, family="cox", steps_n=40)
summary(cox.aic.fit)

y_=sim.data$y
norm.aic.fit = aicreg(xs, NULL, y_, NULL, family="gaussian", steps_n=40)
summary(norm.aic.fit)

ann_tab_cv Fit an Artificial Neural Network model on "tabular" provided as a matrix, optionally allowing for an offset term

Description
Fit an Artificial Neural Network model for analysis of "tabular" data. The model has two hidden layers where the number of terms in each layer is configurable by the user. The activation function can also be switched between relu() (default) gelu() or sigmoid(). Optionally an offset term may be included. Model "family" may be "cox" to fit a generalization of the Cox proportional hazards model, "binomial" to fit a generalization of the logistic regression model and "gaussian" to fit a generalization of linear regression model for a quantitative response. See the corresponding vignette for examples.
ann_tab_cv

Usage

ann_tab_cv(
  myxs,
  mystart = NULL,
  myy,
  myevent = NULL,
  myoffset = NULL,
  family = "binomial",
  fold_n = 5,
  epochs = 200,
  eppr = 40,
  lenz1 = 16,
  lenz2 = 8,
  actv = 1,
  drpot = 0,
  mylr = 0.005,
  wd = 0,
  l1 = 0,
  lasso = 0,
  lscale = 5,
  scale = 1,
  resetlw = 1,
  minloss = 1,
  gotoend = 0,
  seed = NULL,
  foldid = NULL
)

Arguments

myxs  predictor input - an n by p matrix, where n (rows) is sample size, and p (columns) the number of predictors. Must be in matrix form for complete data, no NA's, no Inf’s, etc., and not a data frame.

mystart  an optional vector of start times in case of a Cox model. Class numeric of length same as number of patients (n)

myy  dependent variable as a vector: time, or stop time for Cox model, Y_0 or 1 for binomial (logistic), numeric for gaussian. Must be a vector of length same as number of sample size.

myevent  event indicator, 1 for event, 0 for census, Cox model only. Must be a numeric vector of length same as sample size.

myoffset  an offset term to be used when fitting the ANN. Not yet implemented in its pure form. Functionally an offset can be included in the first column of the predictor or feature matrix myxs and indicated as such using the lasso option.

family  model family, "cox", "binomial" or "gaussian" (default)

fold_n  number of folds for each level of cross validation

epochs  number of epochs to run when tuning on number of epochs for fitting final model number of epochs informed by cross validation
**ann_tab_cv**

---

**eppr**
for EPoch PRint. print summary info every eppr epochs. 0 will print first and last epochs, 0 for first and last epoch, -1 for minimal and -2 for none.

**lenz1**
length of the first hidden layer in the neural network, default 16

**lenz2**
length of the second hidden layer in the neural network, default 16

**actv**
for ACTiVation function. Activation function between layers, 1 for relu, 2 for gelu, 3 for sigmoid.

**drpot**
fraction of weights to randomly zero out. NOT YET implemented.

**mylr**
learning rate for the optimization step in the neural network model fit

**wd**
a possible weight decay for the model fit, default 0 for not considered

**l1**
a possible L1 penalty weight for the model fit, default 0 for not considered

**lasso**
1 to indicate the first column of the input matrix is an offset term, often derived from a lasso model, else 0 (default)

**lscale**
Scale used to allow ReLU to extend +/- lscale before capping the inputted linear estimated

**scale**
Scale used to transform the initial random parameter assignments by dividing by scale

**resetlw**
1 as default to re-adjust weights to account for the offset every epoch. This is only used in case lasso is set to 1.

**minloss**
default of 1 for minimizing loss, else maximizing agreement (concordance for Cox and Binomial, R-square for Gaussian), as function of epochs by cross validation

**gotoend**
fit to the end of epochs. Good for plotting and exploration

**seed**
an optional a numerical/integer vector of length 2, for R and torch random generators, default NULL to generate these. Integers should be positive and not more than 2147483647.

**foldid**
a vector of integers to associate each record to a fold. Should be integers from 1 and fold_n.

---

**Value**
an artificial neural network model fit

---

ann_tab_cv_best, summary.nested.glmnetr, glmnetr.compcv, glmnetr.simdata
**ann_tab_cv_best**

Fit multiple Artificial Neural Network models on "tabular" provided as a matrix, and keep the best one.

**Description**

Fit multiple Artificial Neural Network models for analysis of "tabular" data using `ann_tab_cv()` and select the best fitting model according to cross validation.

**Usage**

```r
ann_tab_cv_best(
  myxs,
  mystart = NULL,
  myy,
  myevent = NULL,
  myoffset = NULL,
  family = "binomial",
  fold_n = 5,
  epochs = 200,
  eppr = 40,
  lenz1 = 32,
  lenz2 = 8,
  actv = 1,
  drpot = 0,
  mylr = 0.005,
  wd = 0,
  l1 = 0,
  lasso = 0,
  lscale = 5,
  scale = 1,
  resetlw = 1,
  minloss = 1,
  gotoend = 0,
  bestof = 10,
  seed = NULL,
  foldid = NULL
)
```

**Arguments**

- **myxs**: predictor input - an `n` by `p` matrix, where `n` (rows) is sample size, and `p` (columns) the number of predictors. Must be in matrix form for complete data, no NA's, no Inf's, etc., and not a data frame.
- **mystart**: an optional vector of start times in case of a Cox model. Class numeric of length same as number of patients (`n`).
**myy**

Dependent variable as a vector: time, or stop time for Cox model, \( Y_0 \) or 1 for binomial (logistic), numeric for gaussian. Must be a vector of length same as number of sample size.

**myevent**

Event indicator, 1 for event, 0 for census, Cox model only. Must be a numeric vector of length same as sample size.

**myoffset**

An offset term to be used when fitting the ANN. Not yet implemented.

**family**

Model family, "cox", "binomial" or "gaussian" (default)

**fold_n**

Number of folds for each level of cross validation

**epochs**

Number of epochs to run when tuning on number of epochs for fitting final model

**number of epochs informed by cross validation**

**eppr**

For Epoch Print. Print summary info every eppr epochs. 0 will print first and last epochs, -1 nothing.

**lent1**

Length of the first hidden layer in the neural network, default 16

**lent2**

Length of the second hidden layer in the neural network, default 16

**actv**

For Activation function. Activation function between layers, 1 for relu, 2 for gelu, 3 for sigmoid.

**drpot**

Fraction of weights to randomly zero out. NOT YET implemented.

**mylr**

Learning rate for the optimization step in the neural network model fit

**wd**

Weight decay for the model fit.

**l1**

A possible L1 penalty weight for the model fit, default 0 for not considered

**lasso**

1 to indicate the first column of the input matrix is an offset term, often derived from a lasso model

**lscale**

Scale used to allow ReLU to extend +/- lscale before capping the inputted linear estimated

**scale**

Scale used to transform the initial random parameter assignments by dividing by scale

**resetlw**

1 as default to re-adjust weights to account for the offset every epoch. This is only used in case lasso is set to 1

**minloss**

Default of 1 for minimizing loss, else maximizing agreement (concordance for Cox and Binomial, R-square for Gaussian), as function of epochs by cross validation

**gotoend**

Fit to the end of epochs. Good for plotting and exploration

**bestof**

How many models to run, from which the best fitting model will be selected.

**seed**

An optional a numerical/integer vector of length 2, for R and torch random generators, default NULL to generate these. Integers should be positive and not more than 2147483647.

**foldid**

A vector of integers to associate each record to a fold. Should be integers from 1 and fold_n.

**Value**

An artificial neural network model fit
best.preds

**Author(s)**
Walter Kremers (kremers.walter@mayo.edu)

**See Also**
ann_tab_cv, nested(glmnet), summary(nested(glmnet), glmnet.compcv, glmnet.simdata

---

**best.preds**

*Get the best models for the steps of a stepreg() fit*

**Description**
Get the best models for the steps of a stepreg() fit

**Usage**

```r
best.preds(modsum, risklist)
```

**Arguments**

- `modsum`: model summary
- `risklist`: riskset list

**Value**

Best predictors at each step of a stepwise regression

---

**bsint**

*Construct the bias terms for going from model layer to layer to carry forward an offset to mimic a linear model*

**Description**

Construct the bias terms for going from model layer to layer to carry forward an offset to mimic a linear model

**Usage**

```r
bsint(tnsr, lasso = 0, rreturn = 1)
```

**Arguments**

- `tnsr`: an input tensor which is to be modified to mimic the linear term of a generalized linear model, e.g. a Cox or logistic regression model
- `lasso`: 1 if the first column is the linear estimate from a linear model, often a lasso model
- `rreturn`: 1 (default) to return an R (numeric) vector, 0 to return a torch tensor
Value

a weight matrix in tensor format

calceloss

calculate cross-entry for multinomial outcomes

Description

calculate cross-entry for multinomial outcomes

Usage

calceloss(xx, yy)

Arguments

xx
the sigmoid of the link, i.e. the estimated probabilities, i.e. xx = 1/(1+exp(-xb))

yy
the observed data as 0's and 1's

Value

the cross-entropy on a per observation basis

cox.sat.dev

Calculate the CoxPH saturated log-likelihood

Description

Calculate the saturated log-likelihood for the Cox model using both the Efron and Breslow approximations for the case where all ties at a common event time have the same weights (exp(X*B)). For the simple case without ties the saturated log-likelihood is 0 as the contribution to the log-likelihood at each event time point can be made arbitrarily close to 1 by assigning a much larger weight to the record with an event. Similarly, in the case of ties one can assign a much larger weight to be associated with one of the event times such that the associated record contributes a 1 to the likelihood. Next one can assign a very large weight to a second tie, but smaller than the first tie considered, and this too will contribute a 1 to the likelihood. Continuing in this way for this and all time points with ties, the partial log-likelihood is 0, just like for the no-ties case. Note, this is the same argument with which we derive the log-likelihood of 0 for the no ties case. Still, to be consistent with others we derive the saturated log-likelihood with ties under the constraint that all ties at each event time carry the same weights.

Usage

cox.sat.dev(y_, e_)
cv.glmnetr

Arguments

\( y_ \)  
Time variable for a survival analysis, whether or not there is a start time.

\( e_ \)  
Event indicator with 1 for event 0 otherwise.

Value

Saturated log likelihood for the Efron and Breslow approximations.

---

cv.glmnetr  
Get a cross validation informed relaxed lasso model fit.

Description

Derive a relaxed lasso model and identifies hyperparameters, i.e. lambda and gamma, which give the best fit using cross validation. It is analogous to the cv.glmnet() function of the 'glmnet' package, but handles cases where glmnet() may run slowly when using the relaxed=TRUE option.

Usage

\[
\text{cv.glmnetr(}
\begin{align*}
\text{xs,} \\
\text{start = NULL,} \\
\text{y_,} \\
\text{event = NULL,} \\
\text{family = "gaussian",} \\
\text{lambda = NULL,} \\
\text{gamma = c(0, 0.25, 0.5, 0.75, 1),} \\
\text{folds_n = 10,} \\
\text{limit = 2,} \\
\text{fine = 0,} \\
\text{track = 0,} \\
\text{seed = NULL,} \\
\text{foldid = NULL,} \\
\text{ties = "efron",} \\
\text{stratified = 1,} \\
\text{time = NULL,} \\
\text{...}
\end{align*}
\)]

Arguments

\( \text{xs} \)  
predictor matrix

\( \text{start} \)  
vector of start times or the Cox model. Should be NULL for other models.

\( \text{y_} \)  
outcome vector

\( \text{event} \)  
event vector in case of the Cox model. May be NULL for other models.
family  model family, "cox", "binomial" or "gaussian" (default)
lambda  the lambda vector. May be NULL.
gamma  the gamma vector. Default is c(0, 0.25, 0.50, 0.75, 1).
folds_n  number of folds for cross validation. Default and generally recommended is 10.
limit  limit the small values for lambda after the initial fit. This will eliminate calculations that have small or minimal impact on the cross validation. Default is 2 for moderate limitation, 1 for less limitation, 0 for none.
fine  use a finer step in determining lambda. Of little value unless one repeats the cross validation many times to more finely tune the hyperparameters. See the 'glmnet' package documentation.
track  indicate whether or not to update progress in the console. Default of 0 suppresses these updates. The option of 1 provides these updates. In fitting clinical data with non full rank design matrix we have found some R-packages to take a very long time or seemingly be caught in infinite loops. Therefore we allow the user to track the program progress and judge whether things are moving forward or if the process should be stopped.
seed  a seed for set.seed() so one can reproduce the model fit. If NULL the program will generate a random seed. Whether specified or NULL, the seed is stored in the output object for future reference. Note, for the default this randomly generated seed depends on the seed in memory at that time so will depend on any calls of set.seed prior to the call of this function.
foldid  a vector of integers to associate each record to a fold. The integers should be between 1 and folds_n.
ties  method for handling ties in Cox model for relaxed model component. Default is "efron", optionally "breslow". For penalized fits "breslow" is always used as in the 'glmnet' package.
stratified  folds are to be constructed stratified on an indicator outcome 1 (default) for yes, 0 for no. Pertains to event variable for "cox" and y_ for "binomial" family.
time  track progress by printing to console elapsed and split times. Suggested to use track option instead as time options will be eliminated.
...  Additional arguments that can be passed to glmnet()

Details

This is the main program for model derivation. As currently implemented the package requires the data to be input as vectors and matrices with no missing values (NA). All data vectors and matrices must be numerical. For factors (categorical variables) one should first construct corresponding numerical variables to represent the factor levels. To take advantage of the lasso model, one can use one hot coding assigning an indicator for each level of each categorical variable, or creating as well other contrasts variables suggested by the subject matter.

Value

A cross validation informed relaxed lasso model fit.
cv.stepreg

x=sim.data$xs
y_=sim.data$y_
event=sim.data$event
# for this example we use a small number for folds_n to shorten run time
cv.glmnetr.fit = cv.glmnetr(xs, NULL, y_, NULL, family="gaussian", folds_n=3, limit=2)
plot(cv.glmnetr.fit)
plot(cv.glmnetr.fit, coefs=1)
summary(cv.glmnetr.fit)

---

cv.stepreg

Cross validation informed stepwise regression model fit.

Description

Cross validation informed stepwise regression model fit.

Usage

cv.stepreg(
  xs_cv,
  start_cv = NULL,
  y_cv,
  event_cv,
  family = "cox",
  steps_n = 0,
  folds_n = 10,
  method = "loglik",
  seed = NULL,
  foldid = NULL,
  stratified = 1,
  track = 0
)

Arguments

xs_cv predictor input - an n by p matrix, where n (rows) is sample size, and p (columns) the number of predictors. Must be in matrix form for complete data, no NA's, no Inf’s, etc., and not a data frame.

start_cv start time, Cox model only - class numeric of length same as number of patients (n)

y_cv output vector: time, or stop time for Cox model, Y_ 0 or 1 for binomial (logistic), numeric for gaussian. # Must be a vector of length same as number of sample size.

event_cv event indicator, 1 for event, 0 for census, Cox model only. Must be a numeric vector of length same as sample size.

family model family, "cox", "binomial" or "gaussian"

steps_n Maximum number of steps done in stepwise regression fitting. If 0, then takes the value rank(xs_cv).

folds_n number of folds for cross validation

method method for choosing model in stepwise procedure, "loglik" or "concordance". Other procedures use the "loglik".

seed a seed for set.seed() to assure one can get the same results twice. If NULL the program will generate a random seed. Whether specified or NULL, the seed is stored in the output object for future reference.

foldid a vector of integers to associate each record to a fold. The integers should be between 1 and folds_n.

stratified folds are to be constructed stratified on an indicator outcome 1 (default) for yes, 0 for no. Pertain to event variable for "cox" and y_ for "binomial" family.

track indicate whether or not to update progress in the console. Default of 0 suppresses these updates. The option of 1 provides these updates. In fitting clinical data with non full rank design matrix we have found some R-packages to take a very long time. Therefore we allow the user to track the program progress and judge whether things are moving forward or if the process should be stopped.

Value
cross validation informed stepwise regression model fit tuned by number of model terms or p-value for inclusion.

Examples

set.seed(955702213)
sim.data=glmnet.simdata(nrows=1000, ncols=100, beta=c(0,1,1))
# this gives a more interesting case but takes longer to run
xs=sim.data$xs
# this will work numerically as an example
xs=sim.data$xs[,c(2,3,50:55)]
dim(xs)
y_=sim.data$yt
event=sim.data$event
# for this example we use small numbers for steps_n and folds_n to shorten run time
cv.stepreg.fit = cv.stepreg(xs, NULL, y_, event, steps_n=10, folds_n=3, track=0)
summary(cv.stepreg.fit)

---

**devrat_**

*Calculate deviance ratios for CV based*

**Description**

Calculate deviance ratios for individual folds and collectively. Calculations are based upon the average -2 Log Likelihoods calculated on each leave out test fold data for the models trained on the other (K-1) folds.

**Usage**

`devrat_(m2.ll.mod, m2.ll.null, m2.ll.sat, n__)`

**Arguments**

- `m2.ll.mod`: -2 Log Likelihoods calculated on the test data
- `m2.ll.null`: -2 Log Likelihoods for the null models
- `m2.ll.sat`: -2 Log Likelihoods for the saturated models
- `n__`: sample size for the individual folds, or number of events for the Cox model

**Value**

A list with `devrat.cv` for the deviance ratios for the individual folds, and `devrat`, a single collective deviance ratio.

---

**diff_time**

*Output to console the elapsed and split times*

**Description**

Output to console the elapsed and split times.

**Usage**

`diff_time(time_start = NULL, time_last = NULL)`

**Arguments**

- `time_start`: beginning time for printing elapsed time
- `time_last`: last time for calculating split time
Value

Time of program invocation

Examples

time_start = diff_time()
time_last = diff_time(time_start)
time_last = diff_time(time_start, time_last)
time_last = diff_time(time_start, time_last)

diff_time1 \quad Get \ elapsed\ time\ in\ c(hour,\ minute,\ secs)

Description

Get elapsed time in c(hour, minute, secs)

Usage

diff_time1(time1, time2)

Arguments

time1 \quad start\ time
time2 \quad stop\ time

Value

Returns a vector of elapsed time in (hour, minute, secs)

dtstndrzent

Standardize\ a\ data\ set

Description

Standardize\ a\ data\ set

Usage

dtstndrzent(datain, lasso = 0)

Arguments

datain \quad The\ data\ matrix\ set\ to\ be\ standardized
lasso \quad 1\ to\ not\ standardize\ the\ first\ column,\ 0\ (default)\ to\ not
**factor.foldid**

*Generate foldid's by factor levels*

**Value**

a standarized data matrix

**Description**

Generate foldid’s by factor levels

**Usage**

`factor.foldid(event, fold_n = 10)`

**Arguments**

- `event`: the outcome variable in a vector identifying the different potential levels of the outcome
- `fold_n`: the numbe of folds to be constructed

**Value**

foldid’s in a vector the same length as event

---

**get.foldid**

*Get foldid’s with branching for cox, binomial and gaussian models*

**Description**

Get foldid’s with branching for cox, binomial and gaussian models

**Usage**

`get.foldid(y_, event, family, folds_n, stratified = 1)`

**Arguments**

- `y_`: see help for cv.glmmnet() or nested.glmmnet()
- `event`: see help for cv.glmmnet() or nested.glmmnet()
- `family`: see help for cv.glmmnet() or nested.glmmnet()
- `folds_n`: see help for cv.glmmnet() or nested.glmmnet()
- `stratified`: see help for cv.glmmnet() or nested.glmmnet()
Value
A numeric vector with foldid’s for use in a cross validation

See Also

 cv.glmnetr, nested.glmnetr, factor.foldid

getlamgam
get numerical values for lam and gam

Description
This function derives the numerical values for lam and gam (lambda and gamma) for usage in plot and predict() functions. If the input variables lam and gam are unspecified then the cross validation informed lambda and gamma values ('lambda.min' and 'gamma.min') which minimize the cross validation deviance, are returned. One may also give lam='lambda.1se' and gam='gamma.1se' to identify the corresponding numerical values. Importantly one may also simply specify gam=1 (and lam=NULL) to get the best lasso fit from the unrelaxed lasso model (gamma=1), or gam=0 (and lam=NULL) to get the best lasso fit from the fully relaxed lasso model (gamma=0).

Usage

getlamgam(object, lam, gam, comment)

Arguments

 object glmnet object as input
 lam value for lam, may be NULL, typically NULL.
 gam value for gam, may be NULL, typically NULL, 0 or 1.
 comment Default of TRUE to write to console information on lam and gam selected for output. FALSE will suppress this write to console.

Value
numerical values for lam and gam for use in plot(), predict() and summary() functions
glmnetr

Fit relaxed part of lasso model

Description

Derive the relaxed lasso fits and optionally calls glmnet() to derive the fully penalized lasso fit.

Usage

glmnetr(
  xs_tmp,
  start_tmp,
  y_tmp,
  event_tmp,
  family = "cox",
  lambda = NULL,
  gamma = c(0, 0.25, 0.5, 0.75, 1),
  object = NULL,
  track = 0,
  ties = "efron",
  time = NULL,
...
)

Arguments

xs_tmp       predictor (X) matrix
start_tmp    start time in case Cox model and (Start, Stop) time for use in model
y_tmp        outcome (Y) variable, in case of Cox model (stop) time
event_tmp    event variable in case of Cox model
family       model family, "cox", "binomial" or "gaussian" (default)
lambda       lambda vector, as in glmnet(), default is NULL
gamma        gamma vector, as with glmnet(), default c(0,0.25,0.5,0.75,1)
object       an output object from glmnet() using relax=FALSE with the model fits for the fully penalized lasso models, i.e. gamma=1. Default is NULL in which case these are derived within the function.
track        Indicate whether or not to update progress in the console. Default of 0 suppresses these updates. The option of 1 provides these updates. In fitting clinical data with non full rank design matrix we have found some R-packages to take a vary long time or possibly get caught in infinite loops. Therefore we allow the user to track the package and judge whether things are moving forward or if the process should be stopped.
ties         method for handling ties in Cox model for relaxed model component. Default is "efron", optionally "breslow". For penalized fits "breslow" is always used as in the 'glmnet' package.
**time**

track progress by printing to console elapsed and split times. Suggested to use
track option instead as time options will be eliminated.

Additional arguments that can be passed to glmnet()

**Value**

A list with two matrices, one for the model coefficients with gamma=1 and the other with gamma=0.

**See Also**

cv.glmmnetr, nested.glmmnetr, glmmnetr.simdata

**Examples**

```r
set.seed(82545037)
sim.data=glmmnetr.simdata(nrows=200, ncols=100, beta=NULL)
xs=sim.data$xs
y_=sim.data$yt
event=sim.data$event
glmmnetr.fit = glmmnetr( xs, NULL, y_, event, family="cox")
plot(glmnetr.fit)
```

---

**glmmnetr.compcv**

*Compare cross validation fits from a nested.glmmnetr output.*

**Description**

Compare cross-validation model fits in terms of average concordance from the nested cross validation fits.

**Usage**

glmmnetr.compcv(object, digits = 4, pow = 1)

**Arguments**

- **object**
  
  A nested.glmmnetr output object.

- **digits**
  
  digits for printing of z-scores, p-values, etc. with default of 4

- **pow**
  
  the power to which the average of correlations is to be raised. Only applies to the "gaussian" model. Default is 2 to yield R-square but can be on to show correlations. pow is ignored for the family of "cox" and "binomial".

**Value**

A printout to the R console.
glmnetr.compcv0

See Also

summary.nested.glmlnetr

Examples

```r
sim.data=glmnetr.simdata(nrows=1000, ncols=100, beta=NULL)
x=sim.data$x
y=sim.data$y
event=sim.data$event
# for this example we use a small number for folds_n to shorten run time
fit3 = nested.glmlnetr(xs, NULL, y_, event, family="cox", folds_n=3)
glmnetr.compcv(fit3)
```

---

glmnetr.compcv0  
*Calculate agreement differences with CI and p*

Description

Perform a paired t-test as called from glmnetr.compcv().

Usage

```r
glmnetr.compcv0(a, b, digits = 4, txt = 0, pow = 1)
```

Arguments

- `a`: One term
- `b`: A second term
- `digits`: digits for printing of z-scores, p-values, etc. with default of 4
- `txt`: 1 (default) to include inline text for estimated, 95 percent CI and p
- `pow`: Power to which the average of correlations is to be raised. Only applies to the "gaussian" model. Default is 2 to yield R-square but can be on to show correlations. Pow is ignored for the family of "cox" and "binomial".

Value

An estimate, 95
**Description**

Generate an example data set with specified number of observations, and predictors. The first column in the design matrix is identically equal to 1 for an intercept. Columns 2 to 5 are for the 4 levels of a character variable, 6 to 11 for the 6 levels of another character variable. Columns 12 to 17 are for 3 binomial predictors, again over parameterized. Such over parameterization can cause difficulties with the `glmnet()` of the 'glmnet' package.

**Usage**

```r
glmnet.simdata(nrows = 1000, ncols = 100, beta = NULL, intr = NULL)
```

**Arguments**

- `nrows` Sample size (>=100) for simulated data, default=1000.
- `ncols` Number of columns (>=17) in design matrix, i.e. predictors, default=100.
- `beta` Vector of length <= ncols for "left most" coefficients. If beta has length < ncols, then the values at length(beta)+1 to ncols are set to 0. Default=NULL, where a beta of length 25 is assigned standard normal values.
- `intr` either NULL for no interactions or a vector of length 3 to impose a product effect as described by `intr[1]*xs[,3]*xs[,8] + intr[2]*xs[,4]*xs[,16] + intr[3]*xs[,18]*xs[,19] + intr[4]*xs[,21]*xs[,22]`

**Value**

A list with elements `xs` for design matrix, `y_` for a quantitative outcome, `yt` for a survival time, event for an indicator of event (1) or censoring (0), in the Cox proportional hazards survival model setting, `yb` for yes/no (binomial) outcome data, and `beta` the beta used in random number generation.

**See Also**

- `glmnetr`,
- `cv.glmnetr`,
- `nested.glmnetr`

**Examples**

```r
sim.data=glmnet.simdata(nrows=1000, ncols=100, beta=NULL)
# for Cox PH survival model data
xs=sim.data$xs
y_=sim.data$yt
event=sim.data$event
# for linear regression model data
xs=sim.data$xs
y_=sim.data$y_
# for logistic regression model data
```
xs=sim.data$xs
y_=sim.data$yb

### glmnetrll_1fold

**Evaluate fit of leave out fold**

#### Description

Derive the log likelihood for a leave out based upon the fit of the input object.

#### Usage

```r
glmnetrll_1fold(
  object,
  xs_new,
  start_new,
  y_new,
  event_new,
  family = "cox",
  lambda_n = NULL,
  gamma = c(0, 0.25, 0.5, 0.75, 1),
  ties = "efron"
)
```

#### Arguments

- **object**: an output object from `cv.glmnet`
- **xs_new**: A new predictor matrix
- **start_new**: A new vector of start times or the Cox model. May be NULL.
- **y_new**: a new outcome vector.
- **event_new**: event vector in case of the Cox model. May be NULL for other models.
- **family**: Model family, one of "cox", "gaussian" or "binomial".
- **lambda_n**: length of the lambda vector.
- **gamma**: The gamma vector.
- **ties**: method for handling ties in Cox model for relaxed model component. Default is "efron", optionally "breslow". For penalized fits "breslow" is always used as in the 'glmnet' package.

#### Value

Returns the log likelihood of object fit using new data.
glmnetr_devratio

Get Deviance ratio.

Description

fit models to derive the deviance ratios.

Usage

```r
glmnetr_devratio(
  object,
  object2,
  xs_new,
  start_new,
  y_new,
  event_new,
  family,
  ties = "efron"
)
```

Arguments

- **object**: a glmnet() output object with relax=FALSE, i.e model fit for gamma=1.
- **object2**: a glmnetr() output object with relaxed fits, i.e model fit for gamma=0.
- **xs_new**: predictor matrix
- **start_new**: start times in case of usage in Cox model. Else should be NULL.
- **y_new**: outcome vector.
- **event_new**: event indicator in case of Cox model. Else should be NULL.
- **family**: model family, one of "cox", "gaussian" or "binomial".
- **ties**: method for handling ties in Cox model for relaxed model component. Default is "efron", optionally "breslow". For penalized fits "breslow" is always used as in the 'glmnet' package.

Value

- Deviance ratios.
glmnetr_seed  Get seeds to store, facilitating replicable results

Description
Get seeds to store, facilitating replicable results

Usage

\[
\text{glmnetr\_seed}(\text{seed, folds\_n = 10, folds\_ann\_n = NULL})
\]

Arguments

- **seed**: The input seed as a start, NULL, a vector of length 1 or 2, or a list with vectors of length 1 or the number of folds, $seedr$ for most models and $seedt$ for the ANN fits
- **folds\_n**: The number of folds in general
- **folds\_ann\_n**: The number of folds for the ANN fits

Value

- seed(s) in a list format for input to subsequent runs

nested.glmnetr  Using nested cross validation, describe and compare fits of various cross validation informed machine learning models.

Description

Performs a nested cross validation for cross validation informed relaxed lasso, Gradient Boosting Machine (GBM), Random Forest (RF), (artificial) Neural Network (ANN) with two hidden layers, Recursive Partitioning (RPART) and step wise regression. That is hyper parameters for all these models are informed by cross validation (CV) (or in the case of RF by out-of-bag calculations), and a second layer of CV (or analogously for the RF) is used to evaluate the performance of these CV informed model fits. For step wise regression CV is used to inform either a p-value for entry or degrees of freedom (df) for the final model choice. For input we require predictors (features) to be in numeric matrix format with no missing values. This is similar to how the glmnet package expects predictors. For survival data we allow input of start time as an option, and require stop time, and an event indicator, 1 for event and 0 for censoring, as separate terms. This may seem unorthodox as it might seem simpler to accept a Surv() object as input. However, multiple packages we use for model fitting models require data in various formats and this choice was the most straightforward for constructing the data formats required. As an example, the XGBoost routines require a data format specific to the XGBoost package, not a matrix, not a data frame. Note, for XGBoost and survival models, only a "stop time" variable, taking a positive value to indicate being associated with an event, and the negative of the time when associated with a censoring, is passed to the input data object for analysis.

Usage

nested.glmnetr(
    xs,
    start = NULL,
    y_,
    event = NULL,
    family = "gaussian",
    do_ncv = 1,
    folds_n = 10,
    stratified = 1,
    dolasso = 1,
    doxgb = 0,
    dorf = 0,
    dorpart = 0,
    doann = 0,
    dostep = 0,
    doaic = 0,
    ensemble = 0,
    method = "loglik",
    lambda = NULL,
    gamma = NULL,
    relax = TRUE,
    steps_n = 0,
    seed = NULL,
    foldid = NULL,
    limit = 1,
    fine = 0,
    ties = "efron",
    keepdata = 0,
    track = 0,
    ...
)

Arguments

xs  predictor input - an n by p matrix, where n (rows) is sample size, and p (columns)
the number of predictors. Must be in matrix form for complete data, no NA's,
no Inf's, etc., and not a data frame.

start  optional start times in case of a Cox model. A numeric (vector) of length same
as number of patients (n). Optionally start may be specified as a column matrix
in which case the colname value is used when outputing summaries.

y_  dependent variable as a vector: time, or stop time for Cox model, Y_ 0 or 1 for
binominal (logistic), numeric for gaussian. Must be a vector of length same as
number of sample size. Optionally y_ may be specified as a column matrix in
which case the colname value is used when outputing summaries.

event  event indicator, 1 for event, 0 for census, Cox model only. Must be a numeric
vector of length same as sample size. Optionally event may be specified as a
column matrix in which case the colname value is used when outputting summaries.

family
model family, "cox", "binomial" or "gaussian" (default)

do_ncv
1 by default to do the Nested Cross Validation, or 0 to only fit the various models without doing the Nested part. In this case the nested.glmnetr() function will only derive the models based upon the full data set. This may be useful when exploring various models without having to the Nested Cross Validation for assessing model performance, for example when wanting to examine a "lasso informed" extreme gradient boosting models (GBM) or Artificial Neural Network (ANN) models which are based upon both a lasso fit and a GBM or ANN fit. See the predict_ann_tab() function regarding getting predicteds for this "lasso informed" models from a nested.glmnetr() output.

folds_n
the number of folds for the outer loop of the nested cross validation, and if not overridden by the individual model specifications, also the number of folds for the inner loop of the nested cross validation, i.e. the number of folds used in model derivation.

stratified
1 to generate fold IDs stratified on outcome or event indicators for the binomial or Cox model.

do_lasso
fit and do cross validation for lasso model, 0 or 1

do_xgb
fit and evaluate a cross validation informed XGBoost (GBM) model. 1 for yes, 0 for no (default). By default the number of folds used when training the GBM model will be the same as the number of folds used in the outer loop of the nested cross validation, and the maximum number of rounds when training the GBM model is set to 1000. To control these values one may specify a list for the doxgb argument. The list can have elements $nfold, $folds, $nrounds and $keep which specify the number of folds, a list with fold ids, the maximum number of rounds when training the GBM model and an indicator whether or not to keep the model fit on the full data. Here we use nomenclature nomenclature used elsewhere in the package to be able to use terms those used in the 'xgboost' package, e.g. nfold instead of folds_n and folds instead of foldid. See xgb.cv() help for more information on these three options. If to shorten run time the user sets nfold to a value other than folds_n we recommend that nfold = folds_n/2 or folds_n/3. Then the folds will be formed by collapsing the folds_n folds allowing a better comparisons of model performances between the different machine learning models. Typically one would want to keep the full data model but the GBM models can cause the output object to require large amounts of storage space so optionally one can choose to not keep the final model when the goal is basically only to assess model performance for the GBM.

dorf
fit and evaluate a random forest (RF) model. 1 for yes, 0 for no (default). Also, if dorf is specified by a list, then RF models will be fit. The randomForestSRC package is used. This list can have three elements. One is the vector mtryc, and contains values for mtry. The program searches over the different values to find a better fit for the final model. If not specified mtryc is set to round(sqrt(dim(xs)[2]) * c(0.67 , 1, 1.5, 2.25, 3.375) ). The second list element the vector ntreec. The first item (ntreec[1]) specifies the number of trees to fit in evaluating the models specified by the different mtry values. The second item (ntreec[2]) specifies the number of trees to fit in the final model. The default is
The third element in the list is the numeric variable keep, with the value 1 (default) to store the model fit on all data in the output object, or the value 0 to not store the full data model fit. Typically one would want to keep the full data model but the RF models can cause the output object to require large amounts of storage space so optionally one can choose to not keep the final model when the goal is basically only to assess model performance for the RF. Random forests use the out-of-bag (OOB) data elements for assessing model fit and hyperparameter tuning and so cross validation is not used for tuning. Still, because of the number of trees in the forest random forest can take long to run.

dorpart
fit and do a nested cross validation for an RPART model. As rpart() does its own approximation for cross validation there is no new functions for cross validation.

doann
fit and evaluate a cross validation informed Artificial Neural Network (ANN) model with two hidden levels. 1 for yes, 0 for no (default). By default the number of folds used when training the ANN model will be the same as the number of folds used in the outer loop of the nested cross validation. To override this, for example to shrtn run time, one may specify a list for the doann argument where the element $folds_ann_n gives the number of folds used when training the ANN. To shorten run we recommend folds_ann_n = folds_n/2 or folds_n/3, and at least 3. Then the folds will be formed by collapsing the folds_n folds using in fitting other models allowing a better comparisons of model performances between the different machine learning models. The list can also have elements $epochs, $epochs2, $myler, $myler2, $eppr, $eppr2, $lenv1, $lenz2, $sactv, $dmpot, $wd, $wd2, $l1, $l12, $lscale, $scale, $minloss and $gotoend. These arguments are then passed to the ann_tab_cv_best() function, with the meanings described in the help for that function, with some exception. When there are two similar values like $epoch and $epoch2 the first applies to the ANN models trained without transfer learning and the second to the models trained with transfer learning from the lasso model. Elements of this list unspecified will take default values. The user may also specify the element $bestof (a positive integer) to fit bestof models with different random starting weights and biases while taking the best performing of the different fits based upon CV as the final model. The default value for bestof is 1.

dostep
fit and do cross validation for stepwise regression fit, 0 or 1, as discussed in James, Witten, Hastie and Tibshirani, 2nd edition.

doaic
fit and do cross validation for AIC fit, 0 or 1. This is provided primarily as a reference.

ensemble
This is a vector 8 characters long and specifies a set of ensemble like model to be fit based upon the predicteds form a relaxed lasso model fit, by either including the predicteds as an additional term (feature) in the machine learning model, or including the predicteds similar to an offset. For XGBoost, the offset is specified in the model with the "base_margin" in the XGBoost call. For the Artificial Neural Network models fit using the ann_tab_cv_best() function, one can initialize model weights (parameters) to account for the predicteds in prediction and either let these weights by modified each epoch or update and maintain these weights during the fitting process. For ensemble[1] = 1 a model is fit ignoring these predicteds, ensemble[2]=1 a model is fit including the predicteds as an additional feature. For ensemble[3]=1 a model is fit using the
predicted as an offset when running the xgboost model, or a model is fit including the predicted with initial weights corresponding to an offset, but then weights are allowed to be tuned over the epochs. For \( i \geq 4 \) ensemble\[i\] only applies to the neural network models. For ensemble\[4\]=1 a model is fit like for ensemble\[3\]=1 but the weights are reassigned to correspond to an offset after each epoch. For \( i \) in \( (5,6,7,8) \) ensemble\[i\] is similar to ensemble\[i-4\] except the original predictor (feature) set is replaced by the set of non-zero terms in the relaxed lasso model fit. If ensemble is specified as 0 or NULL, then ensemble is assigned \( c(1,0,0,0,0,0,0,0) \). If ensemble is specified as 1, then ensemble is assigned \( c(1,1,1,1,1,1,1,1) \).

**method**

method for choosing model in stepwise procedure, "loglik" or "concordance". Other procedures use the "loglik".

**lambda**

lambda vector for the lasso fit

**gamma**

gamma vector for the relaxed lasso fit, default is \( c(0,0.25,0.5,0.75,1) \)

**relax**

fit the relaxed lasso model when fitting a lasso model

**steps_n**

number of steps done in stepwise regression fitting

**seed**

optional, either NULL, or a numerical/integer vector of length 2, for R and torch random generators, or a list with two two vectors, each of length folds\_n+1, for generation of random folds of the outer cross validation loop, and the remaining folds\_n terms for the random generation of the folds or the bootstrap samples for the model fits of the inner loops. This can be used to replicate model fits. Whether specified or NULL, the seed is stored in the output object for future reference. The stored seed is a list with two vectors seedr for the seeds used in generating the random fold splits, and seedt for generating the random initial weights and biases in the torch neural network models. The first element in each of these vectors is for the all data fits and remaining elements for the folds of the inner cross validation. The integers assigned to seed should be positive and not more than 2147483647.

**foldid**

a vector of integers to associate each record to a fold. Should be integers from 1 and folds\_n. These will only be used in the outer folds.

**limit**

limit the small values for lambda after the initial fit. This will have minimal impact on the cross validation. Default is 2 for moderate limitation, 1 for less limitation, 0 for none.

**fine**

use a finer step in determining lambda. Of little value unless one repeats the cross validation many times to more finely tune the hyper parameters. See the 'glmnet' package documentation

**ties**

method for handling ties in Cox model for relaxed model component. Default is "efron", optionally "breslow". For penalized fits "breslow" is always used as derived form to 'glmnet' package.

**keepdata**

0 (default) to delete the input data (xs, start, y_, event) from the output objects from the random forest fit and the glm() fit for the stepwise AIC md=odel, 1 to keep.

**track**

1 (default) to track progress by printing to console elapsed and split times, 0 to not track

... additional arguments that can be passed to glmnet()
Value

- Cross validation informed LASSO, GBM, RPART or STEPWISE model fits, together with estimates of model performance derived using nested cross validation.

glmnetr, cv.glmnetr, glmnetr.simdata, summary.nested.glmnetr, glmnetr.compcv, plot.nested.glmnetr, predict_ann_tab

Examples

sim.data=glmnetr.simdata(nrows=1000, ncols=100, beta=NULL)
xs=sim.data$xs
y_=sim.data$y_
# for this example we use a small number for folds_n to shorten run time
nested.glmnetr.fit = nested.glmnetr( xs, NULL, y_, NULL, family="gaussian", folds_n=3)
plot(nested.glmnetr.fit)
plot(nested.glmnetr.fit, coefs=TRUE)
summary(nested.glmnetr.fit)
summary(nested.glmnetr.fit, cvfit=TRUE)

plot.cv.glmnetr

Plot cross-validation deviances, or model coefficients.

Description

By default, with coefs=FALSE, plots the average deviances as function of lam (lambda) and gam (gamma), and also indicates the gam and lam which minimize deviance based upon a cv.glmnetr() output object. Optionally, with coefs=TRUE, plots the relaxed lasso coefficients.

Usage

## S3 method for class 'cv.glmnetr'
plot(
  x,
  gam = NULL,
  lambda.lo = NULL,
  plup = 0,
  title = NULL,
  coefs = FALSE,
  comment = TRUE,
  ...
)
Arguments

- **x**: a cv.glmnet() output object.
- **gam**: a specific level of gamma for plotting. By default gamma.min will be used.
- **lambda.lo**: a lower limit of lambda when plotting.
- **plup**: an indicator to plot the upper 95 percent two-sided confidence limits.
- **title**: a title for the plot.
- **coefs**: default of FALSE plots deviances, option of TRUE plots coefficients.
- **comment**: default of TRUE to write to console information on lam and gam selected for output. FALSE will suppress this write to console.
- **...**: Additional arguments passed to the plot function.

Value

This program returns a plot to the graphics window, and may provide some numerical information to the R Console. If gam is not specified, then then the gamma.min from the deviance minimizing (lambda.min, gamma.min) pair will be used, and the corresponding lambda.min will be indicated by a vertical line, and the lambda minimizing deviance under the restricted set of models where gamma=0 will be indicated by a second vertical line.

- `plot.glmnetr`
- `plot.nested.glmnetr`
- `cv.glmnetr`

Examples

```r
# set seed for random numbers, optionally, to get reproducible results
set.seed(82545037)
sim.data=glmnetr.simdata(nrows=100, ncols=100, beta=NULL)
xs=sim.data$xs
y_=sim.data$y_
event=sim.data$event
# for this example we use a small number for folds_n to shorten run time
cv_glmnetr_fit = cv.glmnetr(xs, NULL, y_, NULL, family="gaussian", folds_n=3, limit=2)
plot(cv_glmnetr_fit)
plot(cv_glmnetr_fit, coefs=1)
```

Description

Plot the relaxed lasso coefficients from either a glmnetr(), cv.glmnetr() or nested.glmnetr() output object. One may specify gam, single value for gamma. If gam is unspecified (NULL), then cv.glmnetr and nested.glmnetr() will use the gam which minimizes loss, and glmnetr() will use gam=1.
plot.glmnetr

Usage

```r
## S3 method for class 'glmnetr'
plot(x, gam = NULL, lambda.lo = NULL, title = NULL, comment = TRUE, ...)
```

Arguments

- **x**: Either a glmnet, cv.glmnet or a nested.glmnet output object.
- **gam**: A specific level of gamma for plotting. By default gamma.min from the deviance minimizing (lambda.min, gamma.min) pair will be used.
- **lambda.lo**: A lower limit of lambda for plotting.
- **title**: A title for the plot.
- **comment**: Default of TRUE to write to console information on lam and gam selected for output. FALSE will suppress this write to console.
- **...**: Additional arguments passed to the plot function.

Value

This program returns a plot to the graphics window, and may provide some numerical information to the R Console. If the input object is from a nested.glmnet or cv.glmnet object, and gamma is not specified, then the gamma.min from the deviance minimizing (lambda.min, gamma.min) pair will be used, and the minimizing lambda.min will be indicated by a vertical line. Also, if one specifies gam=0, the lambda which minimizes deviance for the restricted set of models where gamma=0 will indicated by a vertical line.

```r
set.seed(82545037)
sim.data=glmnetr.simdata(nrows=200, ncol=100, beta=NULL)
x=sim.data$xs
y_=sim.data$yt
event=sim.data$event
glmnetr.fit = glmnetr( xs, NULL, y_, event, family="cox")
plot(glmnetr.fit)
```
plot.nested.glmnetr  

Plot the nested cross validation performance numbers, cross validated relaxed lasso deviances or coefficients from a nested.glmnetr call. See plot_perf_glmnetr(), plot.cv.glmnetr() and plot.glmnetr().

Description

Plot the nested cross validation performance numbers, cross validated relaxed lasso deviances or coefficients from a nested.glmnetr call. See plot_perf_glmnetr(), plot.cv.glmnetr() and plot.glmnetr().

Usage

```r
## S3 method for class 'nested.glmnetr'
plot(
x,  
type = "lasso",  
gam = NULL,  
lambda.lo = NULL,  
title = NULL,  
plup = 0,  
coefs = FALSE,  
comment = TRUE,  
pow = 2,  
ylim = 1,  
plot = 1,  
fold = 1,  
...)
```

Arguments

- **x**: A nested.glmnetr output object
- **type**: determines what type of plot is to be produced, "lasso" (default) to plot lasso fits. Else nested cross validation performance measures are plotted. Values are "agree" to plot agreement, "lincal" to plot the linear calibration slope coefficients, "intcal" to plot the linear calibration intercept coefficients or "devian" to plot the deviances from the nested cross validation. For each performance measure estimates from the individual (outer) cross validation fold are depicted by thin lines of different colors and styles, while the composite value from all fold=ds is depicted by a thicker black line, and the performance measures naively calculated on the all data using the model derived from all data is depicted in a thicker red line.
- **gam**: A specific level of gamma for plotting. By default gamma.min will be used. Applies only for type = "lasso".
- **lambda.lo**: A lower limit of lambda when plotting. Applies only for type = "lasso".
- **title**: A title
plup

Plot upper 95 percent two-sided confidence intervals for the deviance plots. Applies only for type = "lasso".

coops

Default is FALSE to plot deviances. Option of TRUE to plot coefficients. Applies only for type = "lasso".

coment

Default of TRUE to write to console information on lam and gam selected for output. FALSE will suppress this write to console. Applies only for type = "lasso".

pow

Power to which agreement is to be raised when the "gaussian" model is fit, i.e. 2 for R-square, 1 for correlation. Does not apply to type = "lasso".

ylim

y axis limits for model performance plots, i.e. does not apply to type = "lasso". The ridge model may calibrate very poorly obscuring plots for type of "lincal" or "intcal", so one may specify the ylim value. If ylim is set to 1, then the program will derive a reasonable range for ylim. If ylim is set to 0, then the entire range for all models will be displayed. Does not apply to type = "lasso".

plot

By default 1 to produce a plot, 0 to return the data used in the plot in the form of a list.

fold

By default 1 to display model performance estimates form individual folds when type of "agree", "intcal", "lincal" or "devrat". If 0 then the individual fold calculations are not displayed.

... Additional arguments passed to the plot function.

Value

This program returns a plot to the graphics window, and may provide some numerical information to the R Console.

Examples

```
sim.data=glmnet.simdata(nrows=1000, ncols=100, beta=NULL)
x=x sim.data$xs
y_=sim.data$yt
event=sim.data$event
# for this example we use a small number for folds_n to shorten run time
fit3 = nested.glmnetr(xs, NULL, y_, event, family="cox", folds_n=3)
plot(fit3)
plot(fit3, coefs=TRUE)
```
Function: plot_perf_glmnetr

Description

This function plots summary information from a nested.glmnetr() output object, that is from a nested cross validation performance. Alternatively one can output the numbers otherwise displayed to a list for extraction or customized plotting. Performance measures for plotting include "agree" a measure of agreement, "lincal" the slope from a linear calibration, "intcal" the intercept from a linear calibration, and "devrat" the deviance ratio, i.e. the fractional reduction in deviances relative compared to the null model deviances. Performance measure estimates from the individual (outer) cross validation fold are depicted by thin lines of different colors and styles, while the composite value from all folds is depicted by a thicker black line, and the performance measures naively calculated on the all data using the model derived from all data is depicted by a thicker red line.

Usage

plot_perf_glmnetr(
  x,
  type = "agree",
  pow = 2,
  ylim = 1,
  fold = 1,
  pch = 20,
  plot = 1
)

Arguments

x A nested.glmnetr output object
type determines what type of nested cross validation performance measures are plotted. Possible values are "agree" to plot agreement, "lincal" to plot the linear calibration slope coefficients, "intcal" to plot the linear calibration intercept coefficients or "devrat" to plot the model reduction in deviances relative to the null model deviances, from the nested cross validation.
pow Power to which agreement is to be raised when the "gaussian" model is fit, i.e. 2 for R-square, 1 for correlation. Does not apply to type = "lasso".
ylim y axis limits for model performance plots, i.e. does not apply to type = "lasso". The ridge model may calibrate very poorly obscuring plots for type of "lincal" or "intcal", so one may specify the ylim value. If ylim is set to 1, then the program will derive a reasonable range for ylim. If ylim is set to 0, then the entire range for all models will be displayed. Does not apply to type = "lasso".
fold By default 1 to display using a spaghetti the performance as calculated from the individual folds, 0 to display using dots only the composite values calculated using all folds.
predict.cv.glmnetr

pch  
A number indicating which symbol is to be used in place of the lines when fold=0.

plot  
By default 1 to produce a plot, 0 to return the data used in the plot in the form of a list.

Value  
This program returns a plot to the graphics window by default, and returns a list with data used in the plots if the plot=1 is specified.

plot.glmnetr, plot.cv.glmnetr, plot.nested.glmnetr

predict.cv.glmnetr  
Give predicteds based upon a cv.glmnetr() output object.

Description  
Give predicteds based upon a cv.glmnetr() output object. By default lambda and gamma are chosen as the minimizing values for the relaxed lasso model. If gam=1 and lam=NULL then the best unrelaxed lasso model is chosen and if gam=0 and lam=NULL then the best fully relaxed lasso model is selected.

Usage  
## S3 method for class 'cv.glmnetr'
predict(object, xs_new = NULL, lam = NULL, gam = NULL, comment = TRUE, ...)

Arguments
object  
A cv.glmnetr (or nested.glmnetr) output object.

xs_new  
The predictor matrix. If NULL, then betas are provided.

lam  
The lambda value for choice of beta. If NULL, then lambda.min is used from the cross validated tuned relaxed model. We use the term lam instead of lambda as lambda usually denotes a vector in the package.

gam  
The gamma value for choice of beta. If NULL, then gamma.min is used from the cross validated tuned relaxed model. We use the term gam instead of gamma as gamma usually denotes a vector in the package.

comment  
Default of TRUE to write to console information on lam and gam selected for output. FALSE will suppress this write to console.

...  
Additional arguments passed to the predict function.
predict.cv.stepreg

Value
Either predicteds (xs_new*beta estimates based upon the predictor matrix xs_new) or model coefficients, based upon a cv.glmnetr() output object. When outputting coefficients (beta), creates a list with the first element, beta_, including 0 and non-0 terms and the second element, beta, including only non 0 terms.

See Also
predict.glmnetr, cv.glmnetr, nested.glmnet

Examples
# set seed for random numbers, optionally, to get reproducible results
set.seed(82545037)
sim.data=glmnetr.simdata(nrows=200, ncols=100, beta=NULL)
x$sim.data$x
y_=sim.data$y_
event=sim.data$event
# for this example we use a small number for folds_n to shorten run time
cv.glmnetr.fit = cv.glmnetr(xs, NULL, y_, NULL, family="gaussian", folds_n=3, limit=2)
predict(cv.glmnetr.fit)

predict.cv.stepreg

Beta’s or predicteds based upon a cv.stepreg() output object.

Description
Give predicteds or Beta’s based upon a cv.stepreg() output object. If an input data matrix is specified the X*Beta’s are output. If an input data matrix is not specified then the Beta’s are output. In the first column values are given based upon df as a tuning parameter and in the second column values based upon p as a tuning parameter.

Usage
## S3 method for class 'cv.stepreg'
predict(object, xs = NULL, ...)

Arguments
object cv.stepreg() output object
xs dataset for predictions. Must have the same columns as the input predictor matrix in the call to cv.stepreg().
... pass through parameters

Value
a matrix of beta’s or predicteds
predict.glmnetr  

Get predicteds or coefficients using a glmnetr output object

Description

Give predicteds based upon a glmnetr() output object. Because the glmnetr() function has no cross validation information, lambda and gamma must be specified. To choose lambda and gamma based upon cross validation one may use the cv.glmnetr() or nested.glmnetr() and the corresponding predict() functions.

Usage

## S3 method for class 'glmnetr'
predict(object, xs_new = NULL, lam = NULL, gam = NULL, ...)

Arguments

- **object**: A glmnetr output object
- **xs_new**: A desing matrix for predictions
- **lam**: The value for lambda for determining the lasso fit. Required.
- **gam**: The value for gamma for determining the lasso fit. Required.
- **...**: Additional arguments passed to the predict function.

Value

Coefficients or predictions using a glmnetr output object. When outputting coefficients (beta), creates a list with the first element, beta_, including 0 and non-0 terms and the second element, beta, including only non 0 terms.

See Also

glmnetr, cv.glmnetr, nested.glmnetr

Examples

```R
set.seed(82545037)
sim.data=glmnetr.simdata(nrows=200, ncols=100, beta=NULL)
xs=sim.data$xs
y_=sim.data$yt
event=sim.data$event
glmnetr.fit = glmnetr( xs, NULL, y_, event, family="cox")
betas = predict(glmnetr.fit,NULL,exp(-2),0.5 )
betas$beta
```
predict.nested.glmnetr

Give predicteds based upon the cv.glmnet output object contained in the nested.glmnet output object.

Description

This is essentially a redirect to the summary.cv.glmnet function for nested.glmnet output objects, based upon the cv.glmnet output object contained in the nested.glmnet output object.

Usage

```r
## S3 method for class 'nested.glmnetr'
predict(object, xs_new = NULL, lam = NULL, gam = NULL, comment = TRUE, ...)
```

Arguments

- `object`: A nested.glmnet output object.
- `xs_new`: The predictor matrix. If NULL, then betas are provided.
- `lam`: The lambda value for choice of beta. If NULL, then lambda.min is used from the cross validation informed relaxed model. We use the term lam instead of lambda as lambda usually denotes a vector in the package.
- `gam`: The gamma value for choice of beta. If NULL, then gamma.min is used from the cross validation informed relaxed model. We use the term gam instead of gamma as gamma usually denotes a vector in the package.
- `comment`: Default of TRUE to write to console information on lam and gam selected for output. FALSE will suppress this write to console.
- `...`: Additional arguments passed to the predict function.

Value

Either the xs_new*Beta estimates based upon the predictor matrix, or model coefficients.

See Also

- `predict.cv.glmnet`

Examples

```r
sim.data=glmnetr.simdata(nrows=1000, ncols=100, beta=NULL)
x$sim.data$xs
y_=sim.data$yt
event=sim.data$event
# for this example we use a small number for folds_n to shorten run time
fit3 = nested.glmnetr(xs, NULL, y_, event, family="cox", folds_n=3)
betas = predict(fit3)
```
predict_ann_tab

Get predicteds for an Artificial Neural Network model fit in
nested.glmmnet()

Description

All but one of the Artificial Neural Network (ANNs) fit by nested.glmmnet() are based upon a neural
network model and input from a lasso model. Thus a simple model(xs) statement will not give the
proper predicted values. This function process information form the lasso and ANN model fits to
give the correct predicteds. Whereas the ann_tab_cv() function ca be used to fit a model based upon
an input data set it does not fit a lasso model to allow an informed starting point for the ANN fit.
The pieces fo this are in nested.glmmnet(). To fit a cross validation (CV) informed ANN model fit
one can run nested.glmmnet() with folds_n = 0 to derive the full data models without doing a cross
validation.

Usage

predict_ann_tab(object, xs, modl = NULL)

Arguments

<table>
<thead>
<tr>
<th></th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>object</td>
<td>a output object from the nested.glmmnet() function</td>
</tr>
<tr>
<td>xs</td>
<td>new data of the same form used as input to nested.glmmnet()</td>
</tr>
<tr>
<td>modl</td>
<td>ANN model entry an integer from 1 to 5 indicating which &quot;lasso informed&quot;</td>
</tr>
<tr>

</thead>
<tbody>
<tr>
<td>a vector of predicteds</td>
</tr>
</tbody>
</table>
**prednn_tl**

predicted values from an ann_tab_cv output object based upon the model and its lasso model used for generating an offset

---

**Description**

predicted values from an ann_tab_cv output object based upon the model and its lasso model used for generating an offset

**Usage**

`prednn_tl(lassomod, nnmodel, datain, lasso = 1)`

**Arguments**

- `lassomod`: a lasso model from a glmnetr() call used to generate an offset
- `nnmodel`: a ann_tab_cv() output object for
- `datain`: new data
- `lasso`: 1 if an offset is to be added as column 1 for calculations (default), 0 to subset to the terms significant in a lasso model without adding the offset

**Value**

predictions from a neural network model accounting from a lasso model

---

**preds_1**

*Get predictors form a stepwise regression model.*

---

**Description**

Get predictors form a stepwise regression model.

**Usage**

`preds_1(modsumbest, k_, risklist, risklistl)`

**Arguments**

- `modsumbest`: matrix with best predictors based upon number of model terms
- `k_`: Value for number of predictors in model
- `risklist`: Riskset list
- `risklistl`: Number of terms (length) in the riskset
Value

input to best.preds()

---

print.nested.glmnetr  
*Print an abbreviated summary of a nested.glmnetr() output object*

Description

Print an abbreviated summary of a nested.glmnetr() output object

Usage

```r
## S3 method for class 'nested.glmnetr'
print(x, ...)
```

Arguments

- `x`  
a nested.glmnetr() output object.

- `...`  
additional pass through inputs for the print function.

Value

- a nested cross validation fit summary, or a cross validation model summary.

See Also

`nested.glmnetr`, `glmnetr.compcv`, `summary.nested.glmnetr`

Examples

```r
sim.data=glmnet.simdata(nrows=1000, ncols=100, beta=NULL)
x$sim.data$xs
y_=sim.data$yt
event=sim.data$event
# for this example we use a small number for folds_n to shorten run time
fit3 = nested.glmnetr(xs, NULL, y_, event, family="cox", folds_n=3)
print(fit3)
```
print.rf_tune

Print output from rf_tune() function

Description

Print output from rf_tune() function

Usage

## S3 method for class 'rf_tune'
print(x, ...)

Arguments

x output from an rf_tune() function
... optional pass through parameters to pass to print.rfsrc()

Value

summary to console

rf_tune

Fit a Random Forest model on data provided in matrix and vector formats.

Description

Fit an Random Forest model using the rfsrc() function of the randomForestSRC package.

Usage

rf_tune(
  xs,
  start = NULL,
  y_,
  event = NULL,
  family = NULL,
  mtryc = NULL,
  ntreec = NULL,
  seed = NULL,
  track = 0
)
Arguments

xs  predictor input - an n by p matrix, where n (rows) is sample size, and p (columns) the number of predictors. Must be in matrix form for complete data, no NA's, no Inf’s, etc., and not a data frame.

start  an optional vector of start times in case of a Cox model. Class numeric of length same as number of patients (n)

y_  dependent variable as a vector: time, or stop time for Cox model, Y_ 0 or 1 for binomial (logistic), numeric for gaussian. Must be a vector of length same as number of sample size.

event  event indicator, 1 for event, 0 for census, Cox model only. Must be a numeric vector of length same as sample size.

family  model family, "cox", "binomial" or "gaussian" (default)

mtryc  a vector (numeric) of values to search over for optimization of the Random Forest fit. This if for the mtry input variable of the rfsr() program specifying the number of terms to consider in each step of the Random Forest fit.

ntreecc  a vector (numeric) of 2 values, the first for the number of forests (ntree from rfsr()) to use when searching for a better bit and the second to use when fitting the final model. More trees should give a better fit but require more computations and storage for the final model.

seed  a seed for set.seed() so one can reproduce the model fit. If NULL the program will generate a random seed. Whether specified or NULL, the seed is stored in the output object for future reference. Note, for the default this randomly generated seed depends on the seed in memory at that time so will depend on any calls of set.seed prior to the call of this function.

track  1 to output a brief summary of the final selected model, 2 to output a brief summary on each model fit in search of a better model or 0 (default) to not output this information.

Value

a Random Forest model fit

Author(s)

Walter Kremers (kremers.walter@mayo.edu)
Usage

roundperf(summdf, digits = 3, do_ncv = 1)

Arguments

- **summdf**: a summary data frame from summary.nested.glmnetr() obtained using the option table=0.
- **digits**: the minimum number of decimals to display the elements of the data frame.
- **do_ncv**: 1 (default) if the summdf object is a summary for an analysis including nested cross validation, 0 if only the full data models were fit.

Value

A data frame with the same form as the input but with rounding for easier display.

Description

*Fit the steps of a stepwise regression.*

Usage

```r
stepreg(
x_s_st,
start_time_st = NULL,
y_st,
event_st,
steps_n = 0,
method = "loglik",
family = NULL,
track = 0
)
```

Arguments

- **x_s_st**: predictor input - an n by p matrix, where n (rows) is sample size, and p (columns) the number of predictors. Must be in matrix form for complete data, no NA's, no Inf's, etc., and not a data frame.
- **start_time_st**: start time, Cox model only - class numeric of length same as number of patients (n).
- **y_st**: output vector: time, or stop time for Cox model, y_st 0 or 1 for binomial (logistic), numeric for gaussian. Must be a vector of length same as number of sample size.
**event_st**

event_st indicator, 1 for event, 0 for census, Cox model only. Must be a numeric vector of length same as sample size.

**steps_n**

number of steps done in stepwise regression fitting

**method**

method for choosing model in stepwise procedure, "loglik" or "concordance". Other procedures use the "loglik".

**family**

model family, "cox", "binomial" or "gaussian"

**track**

1 to output stepwise fit program, 0 (default) to suppress

**Value**

does a stepwise regression of depth maximum depth steps_n

**Examples**

```r
set.seed(18306296)
sim.data=glmnetr.simdata(nrows=100, ncols=100, beta=c(0,1,1))
# this gives a more interesting case but takes longer to run
xs=sim.data$xs
# this will work numerically
xs=sim.data$xs[,c(2,3,50:55)]
y_=sim.data$yt
event=sim.data$event
# for a Cox model
cox.step.fit = stepreg(xs, NULL, y_, event, family="cox", steps_n=40)
# ... and for a linear model
y_=sim.data$yt
norm.step.fit = stepreg(xs, NULL, y_, NULL, family="gaussian", steps_n=40)
```

**summary.cv.glmnetr**

Output summary of a cv.glmnetr() output object.

**Description**

Summarize the cross-validation informed model fit. The fully penalized (gamma=1) beta estimate will not be given by default but can too be output using printg1=TRUE.

**Usage**

```r
## S3 method for class 'cv.glmnetr'
summary(object, printg1 = "FALSE", orderall = FALSE, ...)
```
Arguments

object  
a cv.glmnet() output object.
printg1  
TRUE to also print out the fully penalized lasso beta, else FALSE to suppress.
orderall  
By default (orderall=FALSE) the order terms enter into the lasso model is given for the number of terms that enter in lasso minimizing loss model. If orderall=TRUE then all terms that are included in any lasso fit are described.

...  
Additional arguments passed to the summary function.

Value

Coefficient estimates (beta)

See Also

cv.glmnet, nested.glmnet

Examples

# set seed for random numbers, optionally, to get reproducible results
set.seed(82545037)
sim.data=glmnet.simdata(nrows=100, ncols=100, beta=NULL)
xs=sim.data$x
y_=sim.data$y
event=sim.data$event
# for this example we use a small number for folds_n to shorten run time
cv.glmnet.fit = cv.glmnet(xs, NULL, y_, NULL, family="gaussian", folds_n=3, limit=2)
summary(cv.glmnet.fit)
Value

Summary of a stepreg() (stepwise regression) output object.

Examples

```r
set.seed(955702213)
sim.data=glmnetr.simdata(nrows=1000, ncols=100, beta=c(0,1,1))
# this gives a more interesting case but takes longer to run
xs=sim.data$xs
# this will work numerically as an example
xs=sim.data$xs[,c(2,3,50:55)]
dim(xs)
y_=sim.data$yt
event=sim.data$event
# for this example we use small numbers for steps_n and folds_n to shorten run time
cv.stepreg.fit = cv.stepreg(xs, NULL, y_, event, steps_n=10, folds_n=3, track=0)
summary(cv.stepreg.fit)
```

summary.nested.glmnetr

Summarize a nested.glmnetr() output object

Description

Summarize the model fit from a nested.glmnetr() output object, i.e. the fit of a cross-validation informed relaxed lasso model fit, inferred by nested cross validation. Else summarize the cross-validated model fit.

Usage

```r
## S3 method for class 'nested.glmnetr'
summary(
  object,
  cvfit = FALSE,
  pow = 2,
  printg1 = FALSE,
  digits = 4,
  Call = NULL,
  onese = 0,
  table = 1,
  ...
)
```
Arguments

- **object**: a nested.glmnetr() output object.
- **cvfit**: default of FALSE to summarize fit of a cross validation informed relaxed lasso model fit, inferred by nested cross validation. Option of TRUE will describe the cross validation informed relaxed lasso model itself.
- **pow**: the power to which the average of correlations is to be raised. Only applies to the "gaussian" model. Default is 2 to yield R-square but can be on to show correlations. Pow is ignored for the family of "cox" and "binomial".
- **printg1**: TRUE to also print out the fully penalized lasso beta, else to suppress. Only applies to cvfit=TRUE.
- **digits**: digits for printing of deviances, linear calibration coefficients and agreement (concordances and R-squares).
- **Call**: 1 to print call used in generation of the object, 0 or NULL to not print
- **onese**: 0 (default) to not include summary for 1se lasso fits in tables, 1 to include
- **table**: 1 to print table to console, 0 to output the tabled information to a data frame
- **...**: Additional arguments passed to the summary function.

Value

- a nested cross validation fit summary, or a cross validation model summary.

See Also

- glmnetr.compcv, summary.cv.stepreg, nested.glmnetr

Examples

```r
sim.data=glmnetr.simdata(nrows=1000, ncols=100, beta=NULL)
x simul.data$xs
y = sim.data$yt
event = sim.data$event
# for this example we use a small number for folds_n to shorten run time
fit3 = nested.glmnetr(xs, NULL, y, event, family="cox", folds_n=3)
summary(fit3)
```
**summary.rf_tune**

*Summarize output from rf_tune() function*

**Description**

Summarize output from rf_tune() function

**Usage**

```r
## S3 method for class 'rf_tune'
summary(object, ...)
```

**Arguments**

- `object`: output from an rf_tune() function
- `...`: optional pass through parameters to pass to summary.rfsrcc()

**Value**

summary to console

---

**summary.stepreg**

*Briefly summarize steps in a stepreg() output object, i.e. a stepwise regression fit*

**Description**

Briefly summarize steps in a stepreg() output object, i.e. a stepwise regression fit

**Usage**

```r
## S3 method for class 'stepreg'
summary(object, ...)
```

**Arguments**

- `object`: A stepreg() output object
- `...`: Additional arguments passed to the summary function.

**Value**

Summarize a stepreg() object
wtlast

Construct the weights for going from the last hidden layer to the last layer of the model, not counting any activation, to carry forward an offset to mimic a linear model

Description

Construct the weights for going from the last hidden layer to the last layer of the model, not counting any activation, to carry forward an offset to mimic a linear model

Usage

wtlast(tnsr, lasso = 0, lscale = 5, scale = 1, rreturn = 1, trnspose = 0)

Arguments

tnsr an input tensor which is to be modified to mimic the linear term of a generalized linear model, e.g a Cox or logistic regression model
lasso 1 if the first column is the linear estimate from a linear model, often a lasso model
lscale Scale used to allow ReLU to exend +/- lscale before capping the inputted linear estimated
scale Scale used to transform the initial random parameter assignments by dividing by scale
rreturn 1 (default) to return an R (numeric) vector, 0 to return a torch tensor
trnspose 1 to transpose the matrix before returning, 0 to not.

Value

a weight matrix in tensor format

wtmiddle

Construct the weights for going between two hidden layers, carrying forward an offset term to mimic a linear model

Description

Construct the weights for going between two hidden layers, carrying forward an offset term to mimic a linear model

Usage

wtmiddle(tnsr, lasso = 0, rreturn = 1, trnspose = 0)
Arguments

- **tnsr**: an input tensor which is to be modified to mimic the linear term of a generalized linear model, e.g. a Cox or logistic regression model
- **lasso**: 1 if the first column is the linear estimate from a linear model, often a lasso model
- **rreturn**: 1 (default) to return an R (numeric) vector, 0 to return a torch tensor
- **trnspose**: 1 to transpose the matrix before returning, 0 to not.

Value

a weight matrix in tensor format

---

**wtzero**

Construct the weights for going from the observed data with an offset in column 1 to the first hidden layer

Description

Construct the weights for going from the observed data with an offset in column 1 to the first hidden layer

Usage

wtzero(tnsr, lasso = 0, lscale = 5, scale = 1, rreturn = 1, trnspose = 0)

Arguments

- **tnsr**: an input tensor which is to be modified to mimic the linear term of a generalized linear model, e.g. a Cox or logistic regression model
- **lasso**: 1 if the first column is the linear estimate from a linear model, often a lasso model
- **lscale**: Scale used to allow ReLU to extend +/- lscale before capping the inputted linear estimated
- **scale**: Scale used to transform the initial random parameter assignments by dividing by scale
- **rreturn**: 1 (default) to return an R (numeric) vector, 0 to return a torch tensor
- **trnspose**: 1 to transpose the matrix before returning, 0 to not.

Value

a weight matrix in tensor format
Get a simple XGBoost model fit (no tuning)

Description

This fits a gradient boosting machine model using the XGBoost platform. If uses a single set of hyperparameters that have sometimes been reasonable so runs very fast. For a better fit one can use xgb.tuned() which searches for a set of hyperparameters using the mlrMBO package which will generally provide a better fit but take much longer. See xgb.tuned() for a description of the data format required for input.

Usage

xgb.simple(
    train.xgb.dat,
    booster = "gbtree",
    objective = "survival:cox",
    eval_metric = NULL,
    minimize = NULL,
    seed = NULL,
    folds = NULL,
    doxgb = NULL,
    track = 2
)

Arguments

train.xgb.dat The data to be used for training the XGBoost model
booster for now just "gbtree" (default)
objective one of "survival:cox" (default), "binary:logistic" or "reg:squarederror"
eval_metric one of "cox-nloglik" (default), "auc", "rmse" or NULL. Default of NULL will select an appropriate value based upon the objective value.
minimize whether the eval_metric is to be minimized or maximized
seed a seed for set.seed() to assure one can get the same results twice. If NULL the program will generate a random seed. Whether specified or NULL, the seed is stored in the output object for future reference.
folds an optional list where each element is a vector of indexes for a test fold. Default is NULL. If specified then doxgb$nfold is ignored as in xgb.cv().
doxgb a list with parameters for passed to xgb.cv() including $nfold, $nrounds, and $early_stopping_rounds. If not provided defaults will be used. Defaults can be seen from the output object$doxgb element, again a list. In case not NULL, the seed and folds option values override the $seed and $folds values in doxgb.
track 0 (default) to not track progress, 2 to track progress.
xgb.tuned

Get a tuned XGBoost model fit

Description

This fits a gradient boosting machine model using the XGBoost platform. It uses the mlrMBO mlrMBO package to search for a well fitting set of hyperparameters and will generally provide a better fit than xgb.simple(). Both this program and xgb.simple() require data to be provided in a xgb.DMatrix() object. This object can be constructed with a command like data.full <- xgb.DMatrix(data=myxs, label=mylabel), where myxs object contains the predictors (features) in a numerical matrix format with no missing values, and mylabel is the outcome or dependent variable. For logistic regression this would typically be a vector of 0’s and 1’s. For linear regression this would be a vector of numerical values. For a Cox proportional hazards model this would be in a format required for XGBoost, which is different than for the survival package or glmnet package. For the Cox model a vector is used where observations associated with an event are assigned the time of event, and observations associated with censoring are assigned the NEGATIVE of the time of censoring. In this way information about time and status are communicated in a single vector instead of two vectors. The xgb.tuned() function does not handle (start,stop) time, i.e. interval, data. To tune the xgboost model we use the mlrMBO package which "suggests" the DiceKriging and rgenoud packages, but does not install these. Still, for xgb.tuned() to run it seems that one should install the DiceKriging and rgenoud packages.
Usage

xgb.tuned(
    train.xgb.dat,
    booster = "gbtree",
    objective = "survival:cox",
    eval_metric = NULL,
    minimize = NULL,
    seed = NULL,
    folds = NULL,
    doxgb = NULL,
    track = 0
)

Arguments

train.xgb.dat The data to be used for training the XGBoost model
booster for now just "gbtree" (default)
objective one of "survival:cox" (default), "binary:logistic" or "reg:squarederror"
eval_metric one of "cox-nloglik" (default), "auc" or "rmse",
minimize whether the eval_metric is to be minimized or maximized
seed a seed for set.seed() to assure one can get the same results twice. If NULL the program will generate a random seed. Whether specified or NULL, the seed is stored in the output object for future reference.
folds an optional list where each element is a vector of indicies for a test fold. Default is NULL. If specified then nfolds is ignored a la xgb.cv().
doxgb a list with parameters for fitting txgb.cv() including $nfold, $nrounds, and $early_stopping_rounds, each numerical values of length 1, $folds, a list as sued by xgb.cv() do identify folds for cross validation, and $eta, $gamma, $max_depth, $min_child_seight, $colsample_bytree, $lambda, $alpha and $subsample, each a numeric of length 2 giving the lower and upper values for the respective tuning parameter as input into the mlrMBO package functions. If not provided defaults will be used. Defaults can be seen from the output object$doxgb element, again a list. In case not NULL, the seed and folds option values override the $seed and $folds values.
track 0 (default) to not track progress, 2 to track progress.

Value

an XGBoost model fit

Author(s)

Walter K Kremers with contributions from Nicholas B Larson
Examples

# Simulate some data for a Cox model
sim.data=glmnetr.simdata(nrows=1000, ncols=100, beta=NULL)
Surv.xgb = ifelse( sim.data$event==1, sim.data$yt, -sim.data$yt )
data.full <- xgboost::xgb.DMatrix(data = sim.data$xs, label = Surv.xgb)
# for this example we use a small number for folds_n and nrounds to shorten
# run time. This may still take a minute or so.
# xgbfit=xgb.tuned(data.full,objective="survival:cox",nfold=5,nrounds=20)
# preds = predict(xgbfit, sim.data$xs)
# summary( preds )
