Package 'hydroTSM'

March 11, 2020

Type Package

Title Time Series Management, Analysis and Interpolation for Hydrological Modelling

Version 0.6-0

Maintainer Mauricio Zambrano-Bigiarini <mzb.devel@gmail.com>

Description

S3 functions for management, analysis, interpolation and plotting of time series used in hydrology and related environmental sciences. In particular, this package is highly oriented to hydrological modelling tasks. The focus of this package has been put in providing a collection of tools useful for the daily work of hydrologists (although an effort was made to optimise each function as much as possible, functionality has had priority over speed). Bugs / comments / questions / collaboration of any kind are very welcomed, and in particular, datasets that can be included in this package for academic purposes.

License GPL (>= 2)

Depends R (>= 2.10.0), zoo (>= 1.7-2), xts (>= 0.9-7)

Imports e1071, gstat, automap, sp (>= 1.1-0), lattice, maptools, stats, utils, methods, graphics, grDevices

data(OcaEnOnaQts)
monthlyfunction(OcaEnOnaQts, FUN=mean, na.rm=TRUE)
```

5 (sub)daily2annual

Description

Generic function for transforming a (sub)DAILY/MONTHLY (weekly and quarterly) regular time series into an ANNUAL one.

Usage

```
daily2annual(x, ...)
subdaily2annual(x, ...)
monthly2annual(x, ...)
## Default S3 method:
daily2annual(x, FUN, na.rm = TRUE, out.fmt = "%Y", ...)
## S3 method for class 'zoo'
daily2annual(x, FUN, na.rm = TRUE, out.fmt = "%Y-%m-%d", ...)
## S3 method for class 'data.frame'
daily2annual(x, FUN, na.rm = TRUE, out.fmt = "%Y", dates=1,
       date.fmt = "%Y-%m-%d", out.type = "data.frame", verbose = TRUE, ...)
## S3 method for class 'matrix'
daily2annual(x, FUN, na.rm = TRUE, out.fmt = "%Y", dates=1,
        date.fmt = "%Y-%m-%d", out.type = "data.frame", verbose = TRUE, ...)
```

Arguments

zoo, xts, data.frame or matrix object, with (sub)daily/monthly time series. Х

> Measurements at several gauging stations can be stored in a data.frame or matrix object, and in that case, each column of x represent the time series measured in each gauging station, and the column names of x have to correspond to the ID of each station (starting by a letter).

FUN Function that have to be applied for aggregating from (sub)daily/monthly into annual time step (e.g., for precipitation FUN=sum and for temperature and stream-

flows ts, FUN=mean).

Logical. Should missing values be removed? na.rm

> -) TRUE: the monthly and annual values are computed considering only those values different from NA

> -) FALSE: if there is AT LEAST one NA within a year, the corresponding annual value is NA.

out.fmt Character indicating the date format for the output time series. See format in as.Date. Possible values are:

> -) %Y: only the year will be used for the time. Default option. (e.g., "1961" "1962"...)

> -) %Y-%m-%d: a complete date format will be used for the time. (e.g., "1961-01-01" "1962-01-01"...)

numeric, factor or Date object indicating how to obtain the dates for corresponding to each gauging station

dates

6 (sub)daily2annual

If dates is a number (default), it indicates the index of the column in x that stores the dates

If dates is a factor, it is converted into Date class, using the date format specified by date.fmt

If dates is already of Date class, the code verifies that the number of days on it be equal to the number of element in x

date.fmt character indicating the format in which the dates are stored in dates, e.g. %Y-%m-%d.

See format in as. Date.

ONLY required when class(dates)=="factor" or class(dates)=="numeric".

out.type Character that defines the desired type of output. Valid values are:

-) data.frame: a data.frame, with as many columns as stations are included in

x, and row names indicating the Year
-) db: a data.frame, with 3 columns will be produced.

The first column (StationID) will store the ID of the station

The second column (Year) will store the year,

The third column (Value) will contain the annual value corresponding to the two

previous columns.

verbose logical; if TRUE, progress messages are printed

... further arguments passed to or from other methods.

Value

a zoo object with annual frequency

# Sub-daily to monthly ts
subdaily2annual(x, FUN=mean, na.rm=TRUE)

###########
## Ex4: Loading the monthly time series of precipitation within the Ebro River basin
data(EbroPPtsMonthly)

# computing the annual values for the first 10 gauging station in 'EbroPPtsMonthly'
a <- monthly2annual(EbroPPtsMonthly[,1:11], FUN=sum, dates=1)

# same as before, but with a nicer format of years
a <- monthly2annual(EbroPPtsMonthly[,1:11], FUN=sum, dates=1, out.fmt="%Y")

(sub)daily2monthly (sub)Daily -> Monthly
```

Description

Generic function for transforming a DAILY (sub-daily or weekly) regular time series into a MONTHLY one

Usage

Arguments

zoo, xts, data.frame or matrix object, with daily/monthly time series.Measurements at several gauging stations can be stored in a data.frame or matrix

8 (sub)daily2monthly

> object, and in that case, each column of x represent the time series measured in each gauging station, and the column names of x have to correspond to the ID of each station (starting by a letter).

FUN

Function that have to be applied for transforming from daily to annual time step. (e.g., for precipitation FUN=sum and for temperature and streamflow ts, FUN=mean).

na.rm

Logical. Should missing values be removed?

- -) TRUE: the monthly and annual values are computed considering only those values different from NA
- -) FALSE: if there is AT LEAST one NA within a year, the monthly values are NA

numeric, factor or Date object indicating how to obtain the dates for each gauging station

If dates is a number (default), it indicates the index of the column in x that stores the dates

If dates is a factor, it is converted into Date class, using the date format specified by date.fmt

If dates is already of Date class, the code verifies that the number of days on it be equal to the number of elements in x

character indicating the format in which the dates are stored in dates, e.g. %Y-%m-%d. See format in as. Date.

ONLY required when class(dates)=="factor" or class(dates)=="numeric".

out.type

Character that defines the desired type of output. Valid values are:

- -) data. frame: a data.frame, with as many columns as stations are included in x, and row names indicating the month and year for each value.
- -) db: a data.frame, with 4 columns will be produced.

The first column (StationID) stores the ID of the station,

The second column (Year) stores the year The third column (Month) stores the Month

The fourth column (Value) stores the numerical values corresponding to the values specified in the three previous columns.

out.fmt

OPTIONAL. Only used when x is a matrix or data.frame object /cr character, for selecting if the result will be a matrix/data.frame or a zoo object. Valid values are: numeric, zoo.

verbose

logical; if TRUE, progress messages are printed

. . .

further arguments passed to or from other methods.

dates

date.fmt

annualfunction 9

Examples

annualfunction

Annual Function

Description

Generic function for obtaining a SINGLE annual value of a zoo object, by applying any R function to ALL the values in x belonging to the same year, and then applying the same function to ALL the previously computed annual values (e.g., for computing the average annual precipitation or the mean annual streamflow of a long-term time series).

Usage

10 annualfunction

Arguments ×

zoo, xts, data.frame or matrix object, with daily/monthly/annual time series. Measurements at several gauging stations can be stored in a data.frame of matrix object, and in that case, each column of x represent the time series measured in each gauging station, and the column names of x have to correspond to the ID of each station (starting by a letter). FUN Function that will be used to compute the final annual value (e.g., FUN may be some of mean, sum, max, min, sd). Logical. Should missing values be removed?. na.rm -) TRUE: the annual values are computed considering only those values different from NA -) FALSE: if there is AT LEAST one NA within a year, the resulting annual value will be NA numeric, factor or Date object indicating how to obtain the dates corresponding dates to each gauging station. If dates is a number (default), it indicates the index of the column in x that stores the dates If dates is a factor, it have to be converted into Date class, using the date format specified by date.fmt

dates be equal to the number of elements in x

date.fmt character indicating the format in which the dates are stored in *dates*, e.g. %Y-%m-%d.

See format in as. Date.

ONLY required when class(dates)=="factor" or class(dates)=="numeric".

If dates is already of Date class, the code verifies that the number of days in

verbose Logical; if TRUE, progress messages are printed.

further arguments passed to or from other methods.

Value

When x is a time series, a single annual value is returned.

For a data frame, a named vector with the appropriate method being applied column by column.

Note

FUN is first applied to all the values of x belonging to the same year and then it is applied to all the previously computed annual values to get the final result. Its result will depend on the sampling frequency of x and the type of function provided by FUN (**special attention have to be put when** FUN=sum)

climograph 11

Examples

```
## Loading the SanMartino daily precipitation data (1921-1990)
data(SanMartinoPPts)
x <- SanMartinoPPts
# Amount of years in 'x' (needed for computing the average)
nyears <- length( seq(from=time(x[1]), to=time(x[length(x)]), by="years") )
## Average annual precipitation for the 70 years period.
# It is necessary to divide by the amount of years to obtain the average annual value,
# otherwise it will give the total precipitation for all the 70 years.
annualfunction(x, FUN=sum, na.rm=TRUE) / nyears
### verification ####
# Daily to annual
a <- daily2annual(x, FUN=sum, na.rm=TRUE)</pre>
# Mean annual value
mean(a)
##################################
#################################
## Loading the monthly time series of precipitation within the Ebro River basin.
data(EbroPPtsMonthly)
x \leftarrow EbroPPtsMonthly
## Dates of 'x'
dates <- as.Date(x[,1])</pre>
## Computation of the average annual precipitation
## Not run:
## Transforming 'x' into a zoo object
z \leftarrow zoo(x[, 2:ncol(x)], dates)
# Amount of years in 'x' (needed for computing the average)
nyears <- yip(from=start(z), to=end(z), out.type="nmbr" )</pre>
## Average annual precipitation, for the first 5 stations in 'x'
annualfunction(z[,1:5], FUN=sum)/nyears
## End(Not run)
```

12 climograph

Description

Function to draw a climograph based on precipitation and temperature data.

Usage

Arguments

рср	variable of type zoo with monthly, daily or subdaily precipitation data.
tmean	variable of type 'zoo' with monthly, daily or subdaily mean temperature data.
tmx	variable of type 'zoo' with monthly, daily or subdaily maximum temperature data. ONLY used (togheter with tmn) when tmean' is missing.
tmn	variable of type 'zoo' with monthly, daily or subdaily minimum temperature data. ONLY used (togheter with tmx) when tmean is missing.
na.rm	Logical. Should missing values be removed? -) TRUE: the monthly values are computed considering only those values different from NA -) FALSE: if there is AT LEAST one NA within a month, the resulting average monthly value is NA.
main	Character representing the main title of the plot.
pcp.label	Character used in the legend to represent the monthly average precipitation (mostly thought for languages different from English).
tmean.label	Character used in the legend to represent the monthly average temperature (mostly thought for languages different from English).
pcp.col	Color used in the legend to represent the monthly average precipitation.
tmean.col	Color used in the legend to represent the monthly average temperature.
from	OPTIONAL, used for extracting a subset of values. Character indicating the starting date for the values to be extracted. It must be provided in the format specified by date.fmt.
to	OPTIONAL, used for extracting a subset of values. Character indicating the ending date for the values to be extracted. It must be provided in the format specified by date.fmt.
date.fmt	Character indicating the format in which the dates are stored in <i>dates</i> , <i>from</i> and <i>to</i> . See format in as.Date. ONLY required when class(dates)=="factor" or class(dates)=="numeric".

monthlyfunction
```

Examples

dip

Days in Period

Description

Given any starting and ending dates, it generates:

- 1) a vector of class Date with all the days between from and to (both of them included), OR
- 2) the amount of days between the two dates

Usage

```
dip(from, to, date.fmt = "%Y-%m-%d", out.type = "seq")
```

Arguments

from	Character indicating the starting date for creating the sequence. It has to be in the format indicated by date.fmt.
to	Character indicating the ending date for creating the sequence. It has to be in the format indicated by date.fmt.
date.fmt	character indicating the format in which the dates are stored in from and to, e.g. %Y-%m-%d. See format in as.Date. ONLY required when class(dates)=="factor" or class(dates)=="numeric".
out.type	Character indicating the type of result that is given by this function. Valid values are: 1) seq: a vector of class Date with all the days between the two dates, OR 2) nmbr: a single numeric value with the amount of days between the two dates.

14 diy

Value

Depending on the value of out. type, it returns:

- 1) a vector of class Date with all the days between from and to (both of them included), OR
- 2) the amount of days between the two dates

Author(s)

Mauricio Zambrano-Bigiarini, <mzb.devel@gmail>

See Also

```

```

Examples

```
## Sequence of daily dates between "1961-01-01" and "1961-12-31" ##
dip("1961-01-01", "1961-12-31")
## Number of days between "1961-01-01" and "1965-06-30",
## but using "%d-%m-%Y" as date format.
dip("01-01-1961", "30-06-1965", date.fmt= "%d-%m-%Y", out.type = "nmbr")
```

diy

Days in Year

Description

Given a single numeric value representing a year, it generates:

- 1) a vector of dates with all the days within the year, OR
- 2) the amount of days in the specified year

Usage

```
diy(year, out.type = "seq")
```

Arguments

year

numeric, the year for which the sequence of days will be generated

out.type

Character indicating the type of result that is given by this function. Valid values

are:

- -) seq: a vectorial sequence with all the days within the given year
- -) nmbr: the number of days in the vectorial sequence with all the days within the given year

Author(s)

Mauricio Zambrano-Bigiarini, <mzb.devel@gmail>

dm2seasonal 15

See Also

```

dm2seasonal

(sub)Daily/Monthly -> Seasonal Values

Description

Generic function for computing a seasonal value for every year of a sub-daily/daily/weekly/monthly time series

Usage

```
dm2seasonal(x, ...)
subdaily2seasonal(x, ...)

## Default S3 method:
dm2seasonal(x, season, FUN, na.rm = TRUE, out.fmt="%Y", ...)

## S3 method for class 'zoo'
dm2seasonal(x, season, FUN, na.rm = TRUE, out.fmt="%Y", ...)

## S3 method for class 'data.frame'
dm2seasonal(x, season, FUN, na.rm = TRUE, dates=1, date.fmt = "%Y-%m-%d", out.type = "data.frame", out.fmt="%Y", ...)

## S3 method for class 'matrix'
dm2seasonal(x, season, FUN, na.rm = TRUE, dates=1, date.fmt = "%Y-%m-%d", out.type = "data.frame", out.fmt="%Y", ...)
```

Arguments

Х

zoo, xts, data.frame or matrix object, with sub-daily, daily, weekly or monthly time series.

Measurements at several gauging stations can be stored in a data.frame of matrix object, and in that case, each column of x represent the time series measured in each gauging station, and the column names of x have to correspond to the ID of each station (starting by a letter).

16 dm2seasonal

season

character, indicating the weather season to be used for selecting the data. Valid values are:

-) DJF: December, January, February

-) MAM : March, April, May

-) JJA : June, July, August-) SON : September, October, November

-) DJFM: December, January, February, March

-) AM: April, May

-) JJAS: June, July, August, September

-) ON: October, November

FUN

Function that will be applied to ALL the values of x belonging to the given weather season (e.g., FUN can be some of mean, max, min, sd).

The FUN value for the winter season (DJF or DJFM) is computed considering the consecutive months of December, January and February/March. See 'Note' section.

na.rm

Logical. Should missing values be removed?

-) TRUE : the seasonal values are computed considering only those values different from NA (**very important when** FUN=sum)

-) FALSE: if there is AT LEAST one NA within a weather season, the corresponding seasonal values are NA

out.fmt

Character indicating the date format for the output time series. See format in as.Date. Possible values are:

-) %Y: only the year will be used for the time. Default option. (e.g., "1961" "1962"...)

-) %Y-%m-%d: a complete date format will be used for the time. (e.g., "1961-01-01" "1962-01-01"...)

dates

numeric, factor or Date object indicating how to obtain the dates.

If dates is a number (default), it indicates the index of the column in x that stores the dates

If dates is a factor, it is converted into Date class, by using the date format specified by date.fmt

If dates is already of Date class, the code verifies that the number of days on it be equal to the number of elements in x

date.fmt

Character indicating the format in which the dates are stored in *dates*, e.g. %Y-%m-%d. See format in as.Date.

ONLY required when class(dates)=="factor" or class(dates)=="numeric".

out.type

Character that defines the desired type of output. Valid values are:

-) data.frame: a data.frame, with as many columns as stations are included in x, the year corresponding to each seasonal value are used as row names.

-) db: a data.frame, with 4 columns will be produced.

The first column (StationID) stores the ID of the station The second column (Year) stores the year,

The third column (Season) stores the season,

The fourth column (Value) contains the seasonal value corresponding to the values specified in the previous three columns

... further arguments passed to or from other methods.

dm2seasonal 17

Value

A numeric vector with the seasonal values for all the years in which x is defined.

Warning

For any year, the FUN value for the winter season (DJF), is computed considering only January and February, and the value of December is used for computing the winter value of the next year.

Note

FUN is applied to all the values of x belonging to the selected season, so the results of this function depends on the frequency sampling of x and the type of function given by FUN

Author(s)

, hydroplot, seasonalfunction, time2season, extract, daily2monthly, daily2annual, monthly2annual

Examples

18 drawTimeAxis

Description

For a nice time series plot, this function draws a customized time axis, with annual, monthly, daily and sub-daily time marks and labels.

Usage

Arguments

X	time series that will be plotted using the X axis that will be draw $class(x)$ must be ts or zoo
tick.tstep	Character indicating the time step that have to be used for putting the ticks on the time axis. Valid values are: auto, years, quarters, months,weeks, days, hours, minutes, seconds.
lab.tstep	Character indicating the time step that have to be used for putting the labels on the time axis. Valid values are: auto, years, quarters, months, weeks, days, hours, minutes, seconds.
lab.fmt	Character indicating the format to be used for the label of the axis. See format in as.Date. If not specified (lab.fmt=NULL), it will try to use: -) "%Y-%m-%d" when lab.tstep=="days", -) "%b-%Y" when lab.tstep=="year" or lab.tstep=="month".
cex.axis	magnification of axis annotation relative to cex (See par).
mgp	The margin line (in mex units) for the axis title, axis labels and axis line (See par). Default value is $mgp = c(3,2,0)$.
	further arguments passed to the axis function or from other methods.

Note

From version 0.3-0 it changed its name from drawxaxis to drawTimeAxis, in order to have a more intuitive name. The old drawxaxis function is deprecated, but still be kept for compatibility reasons.

dwdays 19

Examples

```
## Loading the SanMartino precipitation data
data(SanMartinoPPts)
x <- window(SanMartinoPPts, end=as.Date("1930-12-31"))

## Plotting the daily ts only, and then automatic 'x' axis
plot(x, xaxt = "n", xlab="Time")
drawTimeAxis(x)

## Plotting the daily ts only, and then monthly ticks in the 'x' axis,
## with annual labels.
plot(x, xaxt = "n", xlab="Time")
drawTimeAxis(x, tick.tstep="months", lab.tstep="years")</pre>
```

dwdays

Amount of dry/wet days in a time series

Description

Given a daily time series (usually precipitation), this function computes the average amount of wet/dry days in each month.

Usage

Arguments

Х

zoo, data.frame or matrix object, usually with daily time series of precipitation. Measurements at several gauging stations can be stored in a data.frame of matrix object, and in that case, each column of x represent the time series measured in each gauging station, and the column names of x have to correspond to the ID of each station (starting by a letter).

thr

numeric. Value of daily precipitation used as threshold for classifying a day as dry/wet or not. Days with a precipitation value larger to thr are classified as wet days, whereas precipitation values lower to thr are classified as dry days.

20 dwi

type	character, indicating if the daily values have to be classified as dry or wet days. It works linked to the values specified in thr. Valid values are: wet, dry.
na.rm	Logical. Should missing values be removed before counting?
dates	numeric, factor or Date object indicating how to obtain the dates If dates is a number (default), it indicates the index of the column in x that stores the dates If dates is a factor, it is converted into Date class, using the date format specified by date.fmt If dates is already of Date class, the code verifies that the number of days in dates be equal to the number of element in x
date.fmt	character indicating the format in which the dates are stored in <i>dates</i> , e.g. %Y-%m-%d. See format in as.Date. ONLY required when class(dates)=="factor" or class(dates)=="numeric".
verbose	logical; if TRUE, progress messages are printed
	further arguments passed to or from other methods.

Author(s)

Examples

```
## Loading the SanMartino precipitation data
data(SanMartinoPPts)
x <- SanMartinoPPts

## Average amount of wet days in each month (for this example, this means days
## with precipitation larger than 0.1mm)
dwdays(x, thr=0.1)</pre>
```

dwi

Days with Information

Description

This function generates a table indicating the number of days with information (<>NA) within a zoo object, aggregated by year, month or month per year.

Usage

dwi 21

Arguments

Х

zoo, data.frame or matrix object, with daily/monthly/annual time series.

Measurements at several gauging stations can be stored in a data.frame of matrix object, and in that case, each column of x represent the time series measured in each gauging station, and the column names of x have to correspond to the ID of each station (starting by a letter).

out.unit

aggregation time for the computation of the amount of days with information. Valid values are:

- -) months: monthly;
- -) years : annual;
- -) mpy: month per year (not available for data.frames)

from

Character indicating the starting date for the computations. It has to be in the format indicated by date.fmt.

When x is a data.frame and this value is not provided, the date corresponding to the first row of x is used

to

Character indicating the ending date for the computations. It has to be in the format indicated by date.fmt.

When x is a data frame and this value is not provided, the date corresponding to the last row of x is used

date.fmt

character indicating the format in which the dates are stored in *dates*, e.g. %Y-%m-%d. See format in as.Date.

ONLY required when class(dates)=="factor" or class(dates)=="numeric".

tstep

Time step used for storing the values in x. Valid values are: days, months, years. Since the version 0.3-0 of hydroTSM, this argument is not required any more, because it is not used any longer.

dates

numeric, factor or Date object indicating how to obtain the dates for each column of \boldsymbol{x}

If dates is a number, it indicates the index of the column in x that stores the dates

If dates is a factor, it is converted into Date class, using the date format specified by date.fmt

If dates is already of Date class, the code verifies that the number of days in dates be equal to the number of element in x

verbose

logical; if TRUE, progress messages are printed

EbroCatchmentsCHE

Subcatchments of the Ebro River basin (Spain)

Description

Shapefile with 57 subcatchments of the Ebro River basin (Spain)

EbroDEM1000m 23

Usage

data(EbroCatchmentsCHE)

Format

SpatialPolygonsDataFrame-class.

The fields stored in the @data slot of this object are:

-) CUECHE: sequential counter

-) CUECHE_ID: ID of each subcatchment

-) NOMBRE: name of each subcatchment

-) AREA_KM2: are of eac subcatchment, [km2]

Details

Projection: European Datum 50, Zone 30N.

Note

A small subcatchment of 0.3 km2 was removed of the original shapefile, due to the fact that it did not have name and it was too small for the purposes of this dataset.

Source

Downloaded ('Divisorias Hidrograficas 1:50.000 - CHE') from the web site of the Confederacion Hidrografica del Ebro (CHE) http://www.chebro.es/ (original link http://oph.chebro.es/ContenidoCartoHidrologia.htm, last accessed [March 2008]).

EbroDEM1000m

Digital Elevation Model (DEM) of the Ebro River basin (Spain)

Description

Digital Elevation Model of the Ebro River basin (Spain), with cells of 1000x1000 [m]

Usage

data(EbroDEM1000m)

Format

'SpatialGridDataFrame'

Details

Digital elevation model of the Ebro River basin, with 1000x1000m of spatial resolution.

24 EbroPPgis

Source

The original file (Modelo Digital MDT200 RASTER) was downloaded from the web site of the Confederacion Hidrografica del Ebro (CHE) http://www.chebro.es/ (original link http://oph.chebro.es/ContenidoCartoAplast accessed [March 2010]), and then resampled up to 1000x1000m of resolution.

This dataset is intended to be used for research purposes only, being distributed in the hope that it will be useful, but WITHOUT ANY WARRANTY.

EbroPPgis

Spatial location of raingauges on the Ebro River basin

Description

Spatial location of the 349 raingauges with daily precipitation on the Ebro River Basin (dataset 'EbroPPts'), Spain, with more than 70% of days with information (without missing values)

Usage

data(EbroPPgis)

Format

A data.frame with seven fields:

- *) 'ID: identifier of each gauging station.
- *) 'STATION_NAME' : name of the gauging station.
- *) 'EAST_ED50': easting coordinate of the gauging station. European Datum 50, Zone 30 North.
- *) 'NORTH_ED50' : northing coordinate of the gauging station. European Datum 50, Zone 30 North.
- *) 'ELEVATION': elevation of the gauging station, [m a.s.l.].
- *) 'CHE_BASIN_ID': identifier of the subbasin in which the gauging station s located.
- *) 'CHE_BASIN_NAME': name of the subbasin in which the gauging station s located.

Details

Projection: European Datum 50, Zone 30N.

Source

Downloaded ('Red de Control Meteorologico') from the web site of the Confederacion Hidrografica del Ebro (CHE) http://www.chebro.es/ (original link http://oph.chebro.es/ContenidoCartoClimatologia.htm, last accessed [March 2008]), and then the name of 7 selected fields were translated into English language.

These data are intended to be used for research purposes only, being distributed in the hope that it will be useful, but WITHOUT ANY WARRANTY.

EbroPPtsMonthly 25

EbroPPtsMonthly

Ebro Monthly Precipitation Time Series

Description

Time series of monthly precipitation on 331 stations of the Ebro River basin (NW Spain), for the period January/1961 to December/1963.

Usage

```
data(EbroPPtsMonthly)
```

Format

A data frame with 331 monthly time series, plus the first field storing the dates corresponding to each row.

Details

Monthly time series of precipitation on 331 stations of the Ebro River basin (Spain), where some data were in-filled by using the MOSS method and from daily time series used in the technical report "Estudio de Recursos de la Cuenca del Ebro".

Source

Downloaded from the web site of the Confederacion Hidrografica del Ebro (CHE) http://www.chebro.es/ (original link <a href="http://oph.chebro.es/DOCUMENTACION/PrecipitacionMensualRelleno/Pre

extract

Extract from Zoo

Description

Extracts from a zoo object all the values belonging to a given month, year or weather season.

Usage

```
extract(x, ...)
## Default S3 method:
extract(x, trgt, ...)
## S3 method for class 'zoo'
extract(x, trgt, ...)
```

26 extract

Arguments

x zoo object

trgt

numeric or character indicating the elements to extract from x. Valid values are: 1) integer(s) from 1 to 12: trgt is considered as month(s) (1=JAN, 2=FEB,...., 12=DEC), and all the values in x belonging to the month(s) specified by trgt will be extracted.

- 2) integer(s) > 12: trgt is considered as year(s), and all the values in x belonging to the year(s) specified by trgt will be extracted
- 3) character: trgt is considered as a weather season, and all the values in x belonging to the season specified by trgt will be extracted. Valid values are:
- -) DJF: December, January, February
- -) MAM: March, April, May -) JJA: June, July, August
- -) SON: September, October, November
- -) DJFM: December, January, February, March
- -) AM: April, May
- -) JJAS: June, July, August, September
- -) ON: October, November

... further arguments passed to or from other methods

Value

a zoo object with the extracted values.

     leg.cex=1, leg.pos="topright", verbose=TRUE, thr.shw=TRUE, new=TRUE, ...)
```

28 fdc

Arguments

numeric, zoo, data.frame or matrix object with the observed streamflows for Х which the flow duration curve have to be computed. Measurements at several gauging stations can be stored in a data.frame of matrix object, and in that case, each column of x represent the time series measured in each gauging station, and the column names of x have to correspond to the ID of each station (starting by a letter). When x is a matrix or data frame, the flow duration curve is computed for each column. 10.thr numeric, low-flow separation threshold. If this value is different from NA, a vertical line is drawn in this value, and all the values to the right of it should be deemed as low flows. Default value is 0.7. hQ.thr numeric, high-flow separation threshold. If this value is different from NA, a vertical line is drawn in this value, and all the values to the left of it should br deemed as high flows. Default value is 0.2. plot logical. Indicates if the flow duration curve should be plotted or not. Default value is TRUE. character, indicates which axis has to be plotted with a logarithmic scale. Default log value is y main See plot. An overall title for the plot: see title. xlab A title for the x axis. See plot. ylab A title for the y axis. See plot. The y limits of the plot. See plot.default. ylim Only used when log="y". yat numeric, with points at which tick-marks will try to be drawn in the Y axis, in addition to the defaults computed by R. See the at argument in Axis. xat Only used when log="x". numeric, with points at which tick-marks will try to be drawn in the x axis, in addition to the defaults computed by R. See the at argument in Axis. The colors to be used for lines and points. Multiple colors can be specified so col that each point can be given its own color. If there are fewer colors than points they are recycled in the standard fashion. Lines will all be plotted in the first colour specified. See plot.default. A vector of plotting characters or symbols: see points. See plot.default. pch lwd The line width, see par. See plot.default. The line type, see par. See plot. default. lty See plot.default. A numerical vector giving the amount by which plotting cex characters and symbols should be scaled relative to the default. This works as a multiple of par("cex"). 'NULL' and 'NA' are equivalent to '1.0'. Note that this does not affect annotation cex.axis magnification of axis annotation relative to 'cex'. cex.lab Magnification to be used for x and y labels relative to the current setting of 'cex'. See '?par'. leg.txt vector with the names that have to be used for each column of x.

fdc 29

leg.cex	numeric, indicating the character expansion factor for the legend, *relative* to current par("cex"). Default value = 1
leg.pos	keyword to be used to position the legend. One of the list '"bottomright", "bottom", "bottomleft", "left", "topleft", "top", "topright", "right", "center". This places the legend on the inside of the plot frame at the given location. See legend.
verbose	logical; if TRUE, progress messages are printed (when x is a matrix or data.frame).
thr.shw	logical, indicating if the streamflow values corresponding to the user-defined thresholds 1Q. thr and hQ. thr have to be shown in the plot.
new	logical, if TRUE (default), a new plotting window is created.
	further arguments passed to or from other methods (to the plotting functions)

Value

numeric, matrix or data.frame whose columns contains the % of time each one of the streamflow magnitudes given as input was equalled or exceeded. The resulting values have to be multiplied by 100 to get a percentage.

When plot is TRUE (default), the resulting flow duration curve is plotted in a new window.

```

Arguments

Χ

numeric, zoo, data.frame or matrix object with the observed streamflows for which the flow duration curve have to be computed.

Measurements at several gauging stations can be stored in a data.frame of matrix object, and in that case, each column of x represent the time series measured in each gauging station, and the column names of x have to correspond to the ID of each station (starting by a letter). When x is a matrix or data.frame, the flow duration curve is computed for each column.

1band

numeric, zoo, data.frame or matrix object with the streamflows representing the the lower uncertainty bound of x, for which the flow duration curve have to be computed.

Measurements at several gauging stations can be stored in a data.frame of matrix object. When 1band is a matrix or data.frame, the flow duration curve is

computed for each column.

uband numeric, zoo, data.frame or matrix object with the streamflows representing the

the upper uncertainty bound of x, for which the flow duration curve have to be

computed.

Measurements at several gauging stations can be stored in a data.frame of matrix object. When uband is a matrix or data.frame, the flow duration curve is computed for each column.

sim OPTIONAL.

numeric, zoo, data.frame or matrix object with the streamflows simulated for x, for which the flow duration curve have to be computed.

Measurements at several gauging stations can be stored in a data.frame of matrix object. When sim is a matrix or data.frame, the flow duration curve is computed

for each column.

1Q. thr numeric, low flows separation threshold. If this value is different from 'NA', a vertical line is drawn in this value, and all the values to the left of it are deemed

low flows.

hQ. thr numeric, high flows separation threshold. If this value is different from 'NA', a

vertical line is drawn in this value, and all the values to the right of it are deemed

high flows

plot logical. Indicates if the flow duration curve should be plotted or not.

log character, indicates which axis has to be plotted with a logarithmic scale. Default

value is y.

main See plot. An overall title for the plot: see title.

xlab See plot. A title for the x axis: see title.

ylab See plot. A title for the y axis: see title.

ylim See plot. default. The y limits of the plot.

yat Only used when log="y".

numeric, with points at which tick-marks will try to be drawn in the Y axis, in

addition to the defaults computed by R. See the at argument in Axis.

xat Only used when log="x".

col

numeric, with points at which tick-marks will try to be drawn in the x axis, in

addition to the defaults computed by R. See the at argument in Axis.

See plot.default. The colors for lines and points. Multiple colors can be specified so that each point can be given its own color. If there are fewer colors than points they are recycled in the standard fashion. Lines will all be plotted in

the first colour specified.

pch See plot.default. A vector of plotting characters or symbols: see points.

lwd See plot. default. The line width, see par.

lty See plot. default. The line type, see par.

cex See plot.default. A numerical vector giving the amount by which plotting characters and symbols should be scaled relative to the default. This works as

a multiple of par("cex"). 'NULL' and 'NA' are equivalent to '1.0'. Note that

this does not affect annotation.

cex.axis	magnification of axis annotation relative to 'cex'.
cex.lab	Magnification to be used for x and y labels relative to the current setting of 'cex'. See '?par'.
leg.txt	vector with the names that have to be used for each column of x.
leg.cex	numeric, indicating the character expansion factor for the legend, *relative* to current par("cex"). Default value = 1
leg.pos	keyword to be used to position the legend. One of the list '"bottomright", "bottom", "bottomleft", "left", "topleft", "top", "topright", "right", "center". This places the legend on the inside of the plot frame at the given location. See legend. When leg.pos="auto", the legend provided by leg.txt is located on the 'bottomleft' when log="y" and on the 'topright' otherwise
verbose	logical; if TRUE, progress messages are printed
thr.shw	logical, indicating if the streamflow values corresponding to the user-defined thresholds 1Q. thr and hQ. thr have to be shown in the plot. When leg.pos="auto", the legend with the threshold values is located on the 'topright' when log="y" and on the 'bottomleft' otherwise
border	See polygon. The color to draw the border of the polygon with the uncertainty bounds. The default, 'NA', means to omit borders.
bands.col	See polygon. The color for filling the polygon. The default, 'NA', is to leave polygons unfilled, unless bands.density is specified. If bands.density is specified with a positive value this gives the color of the shading lines.
bands.density	See polygon. The density of shading lines for the polygon with the uncertainty bounds, in lines per inch. The default value of 'NULL' means that no shading lines are drawn. A zero value of bands.density means no shading nor filling whereas negative values (and 'NA') suppress shading (and so allow color filling).
bands.angle	See polygon. The slope of shading lines for the polygon with the uncertainty bounds, given as an angle in degrees (counter-clockwise).
new	logical, if TRUE, a new plotting window is created.
	further arguments passed to or from other methods (to the plotting functions)

Note

If you do not want to use logarithmic scale for the streamflow axis, you can do it by passing the log="" to the . . . argument.

gists2spt

Time Series and GIS Info -> (pseudo)Spatio-Temporal Object

Description

Given a data.frame (x.gis) with the spatial coordinates of a set of measurement points (e.g., gauging stations) and the measurements in those stations (x.ts) this function merges the measurements in x.ts with the corresponding spatial location in x.gis, even if they are not in the same order.

If the spatial coordinates X and Y are given for x.gis, the resulting object will be a SpatialPointsDataFrameclass with coordinates given by the X and Y fields

If p4s is given, the resulting object will be projected according to the specification provided by p4s.

Usage

gists2spt 35

Arguments

data frame with the spatial information for all the measurement points in x.gis. x.gis The name of each station, stored in the field sname, have to be equal to the corresponding ID used in x.ts -) It MAY contain as many measurement points as you want, e.g., all the gauging stations in your database, but -) It HAVE TO contain -at least- the location of the measurement points of x. ts that will be used for the interpolations. The MINIMUM fields that HAVE TO be present in this file, and their corresponding column index are X, Y, sname. numeric or data.frame with the measured value at each station for a given time. x.ts Each value of x. ts has to have as name (names(x.ts)) the ID of the station. 1) It MAY contain as many stations as you want, e.g., all the gauging stations in the your database, but 2) It HAVE TO contain -at least- some stations of x.gis sname character, field name in x.gis that stores the name of the stations (the name of the stations have to start by a letter !!) OPTIONAL. character, field name in x.gis that stores the name of the subbname catchment in x.gis that will be analysed. ONLY necessary when 'catchment.name' is not "all" Χ character, field name in x.gis that stores the easting coordinate of the measurement points. The expected name is 'x', but if the value provided by the user is different, a new 'x' field is created and is used as the easting coordinate of x.gis Υ character, field name in x.gis that stores the northing coordinate of the measurement points. The expected name is 'y', but if the value provided by the user is different, a new 'y' field is created and is used as the northing coordinate of x.gis elevation OPTIONAL. character, field name x.gis that stores the elevation of the stations (m a.s.l.). catchment.name name of the catchment that will be analysed. Possible values are: -)all: ALL the stations in the x.gis will be used -)other character: ONLY those stations in x.gis with a bname field value == catchment.name will be used. Character with information about the projection of the GIS files, usually created p4s by the CRS function of the sp package

Value

na.rm

If p4s is given, the returning object will be a SpatialPointsDataFrame-class, if not, it will be a data.frame

a logical value indicating whether 'NA' values should be stripped before deliv-

Hours in Period

Description

Given any starting and ending date/time objects, it generates:

- 1) a vector of class c("POSIXct" "POSIXt") with all the hours between the two date/time objects (both of them included), OR
- 2) the amount of hours between the two date/time objects

Usage

```
hip(from, to, date.fmt="%Y-%m-%d %H", out.type = "seq")
```

hip 37

Arguments

Character or POSIXct object indicating the starting date/time for creating the sequence. It has to be in the format indicated by date.fmt.
Character indicating the ending date/time for creating the sequence. It has to be in the format indicated by date.fmt.
character indicating the format in which the date/time objects are stored in from and to, e.g. %Y-%m-%d %H:%M. See format in as.Date. ONLY required when class(dates)=="factor" or class(dates)=="numeric".
Character indicating the type of result that is given by this function. Valid values are: 1) seq: a vector of class Date with all the days between the two dates, OR 2) nmbr: a single numeric value with the amount of days between the two dates.

Value

Depending on the value of out. type, it returns:

- 1) a vector of class c("POSIXct"" POSIXt") with all the hours between from and to (both of them included), OR
- 2) the amount of hours between the two date/time objects

hydrokrige

Krige for Hydrological Time Series

Description

Automatic interpolation for hydrological ts, with optional plot (wrapper to some functions of the **gstat** and **automap** packages)

Originally it was thought as a way to make easier the computation of average precipitation over subcatchments (given as input in a shapefile map), based on values measured at several gauging stations, but nowadays it can also be used for interpolating any variable over a grid given by a raster map.

Available algorithms: inverse distance weighted (IDW), ordinary kriging (OK) and kriging with external drift (KED)

The (Block) Inverse Distance Weighted (IDW) interpolation is a wrapper to the idw function of the **gstat** package (so, it requires the **gstat** package).

The automatic kriging (OK or KED) is a wrapper to the autoKrige function of the automap package (so, it requires the automap and gstat packages), which automatically selects the best variogram model from four different ones: spherical, exponential, gaussian and Matern with M. Stein's parameterization (for more details, see autoKrige)

Usage

```
hydrokrige(x.ts, x.gis, ...)
## Default S3 method:
hydrokrige(x.ts, x.gis, X= "x", Y= "y", sname, bname,
        elevation, predictors, catchment.name = "all", type="cells",
        formula, subcatchments, IDvar = NULL,
       p4s=CRS(as.character(NA)), cell.size = 1000,
       grid.type = "regular", nmin = 0, nmax = Inf, maxdist = Inf,
       ColorRamp = "PCPAnomaly", plot = TRUE, col.nintv = 10,
        col.at = "auto", main, stations.plot = FALSE, stations.offset,
        arrow.plot = FALSE, arrow.offset, arrow.scale,
        scalebar.plot = FALSE, sb.offset, sb.scale, verbose = TRUE,
       allNA.action="error", ...)
## S3 method for class 'data.frame'
hydrokrige(x.ts, x.gis, X= "x", Y= "y", sname, bname,
       elevation, predictors, catchment.name = "all", type = "block",
        formula, subcatchments, IDvar= NULL,
        p4s=CRS(as.character(NA)), cell.size = 1000,
```

```
grid.type = "regular", nmin = 0, nmax = Inf, maxdist = Inf,
ColorRamp = "PCPAnomaly", plot = FALSE, col.nintv = 10,
col.at = "auto", main, stations.plot = FALSE, stations.offset,
arrow.plot = FALSE, arrow.offset, arrow.scale,
scalebar.plot = FALSE, sb.offset, sb.scale,
verbose = TRUE, allNA.action="error",
dates=1, from, to, write2disk = TRUE,
out.fmt= "csv2",
fname = paste(ColorRamp, "by_Subcatch.csv", sep = ""), ...)
```

Arguments

x.ts numeric or data frame object, with measured values at several locations.

- -) x.ts CAN contain as many points as you want, e.g., all the gauging stations in the your database.
- 2) x.ts HAVE to contain -at least- some points (e.g., gauging stations) that are also present in x.gis

The names of each value in x.ts are used as the ID of each measurement point. When x.ts is a vector, this can be checked with names(x), whereas when x.ts is a data.frame, it can be checked with colnames(x.ts). The IDs of each measurement point have to be equal to the ID stored in the field sname of x.gis.

When x. ts is a data.frame, its structure have to be as follow:

- -) 1st column : OPTIONAL. It MAY contain the dates, date-time or IDs that identify the measured values of each row. See dates argument.
- -) 2nd...Nth column: Measured values at each point (e.g., gauging station). The name of the columns is used as the ID of each station -starting with a letter!!-.
- data.frame with the spatial information for each measurement point (e.g., gauging stations).
 - -) x.gis MAY contain as many points as you want, e.g., all the stations in your database
 - -) x.gis HAVE to contain -at least- the location of those stations that will be used for the interpolations

The MINIMUM fields that have to be present in this file, and their corresponding column index are those described by: X, Y, sname.

The ID of each measurement point, given in the field sname, has to be equal to the corresponding ID used in x.ts

- character, field name in x.gis that stores the easting coordinate of each measurement point.
- character, field name in x.gis that stores the northing coordinate of each measurement point.

x.gis

Χ

Υ

character, field name in x.gis that stores the ID of each measurement point. the sname

name of each measurement point HAS to start by a letter!!-

bname OPTIONAL. character, field name in x.gis that stores the name of the sub-

catchment in x.gis that will be analysed.

ONLY necessary when catchment.name is different from all.

elevation OPTIONAL. character, field name in x.gis that stores the elevation of the gaug-

ing stations (m a.s.l.).

OPTIONAL. SpatialGridDataFrame-class object, with prediction/simulation lopredictors

cations (it is needed for KED).

Usually, a digital elevation model (DEM) read with the readGDAL function of the **rgdal** package. See the newdata argument in krige.

It should contain attribute columns with the independent variables (if present) and the coordinates with names as defined in x.gis

If predictors is missing, the grid to be used as prediction/simulation locations is generated from sampling the polygon specified by the user in subcatchments, according to the arguments provided by cells. size and grid. type

catchment.name name of the catchment that will be analysed. Possible values are:

-)all: ALL the stations in the x.gis will be used

-)other string: ONLY those stations in x.gis with a bname field value equal to catchment.name will be used.

Character, indicating the type of interpolation required by the user.

When x. ts is a data frame, the ONLY possible value is block. For all the other cases, possible values are:

-) cells: the interpolated values are computed for each cell

-) block: the interpolated values are computed for each subcatchment, where the value for each subcatchment is computed as the mean value over all the cells that belong to each subcatchment

-) both: cells and block are computed.

formula OPTIONAL. Formula to be used in case of ordinary kriging or kriging with ex-

> ternal drift. Requires the **automap** package. All the variables to be used within formula has to be present both in x.gis and predictors. See the formula

argument in krige.

formula defines the dependent variable as a linear model of independent variables. Within this function, the dependent variable is always called value, therefore, for ordinary and simple kriging use the formula value~1; for simple kriging also define beta; for universal kriging, suppose value is linearly

dependent on x and y, use the formula value~x+y.

subcatchments OPTIONAL. Only required when predictors is missing.

> Spatial polygon with all the subcatchments to be used as interpolation domain. The polygons are used to create the grid that will be used as prediction/simulation locations, from sampling it according to the arguments provided by cells.size and grid. type. Valid values are:

- 1) Character, indicating the filename (with path) of the shapefile that contains all the subcatchments to be used as interpolation domain. It HAS TO BE of 'polygon' type
- 2) SpatialPolygonsDataFrame-class resulting from reading the shapefile (e.g.,

type

> with the command readShapePoly of the maptools package) that contains all the subcatchments to be used as interpolation domain.

IDvar

See readShapePoly. a character string with the name of a field in the subcatchments shapefile containing the ID values used to identify each one of the subcatchments. When type is block, the values stored in this field will be used for labelling the computed values in each one of the subcatchments, therefore, if you don't provide this value, it could be difficult to identify which computed value corresponds to which subcatchment, because the ID is assigned by the readShapePoly function.

p4s

OPTIONAL. a character with information about the projection of the GIS files, usually created by the CRS function of the **sp** package.

cell.size

OPTIONAL. Only required when predictors is missing. Size of the cells [m] to be used for sampling the polygons specified by the user in subcatchments, to create a grid to be used as prediction/simulation locations.

grid.type

OPTIONAL. Only required when predictors is missing. See spsample. Character, indicating the type of grid to be computed over the area defined by subcatchments. Valid values are:

-) regular: for regular (systematically aligned) sampling; Default option

-) random: for completely spatial random;

-) stratified: for stratified random (one single random location in each "cell" -) nonaligned: for non-aligned systematic sampling (nx random y coordinates, ny random x coordinates);

-) hexagonal: for sampling on a hexagonal lattice;

-) clustered: for clustered sampling

OPTIONAL. See krige. For local interpolation: if the number of nearest observations within distance maxdist is less than nmin, a missing value will be generated; see maxdist. By default nmin=0.

nmax

OPTIONAL. See krige. For local interpolation: the number of nearest observations that should be used for a kriging prediction, where nearest is defined in terms of the space of the spatial locations. By default, all observations are used.

maxdist

OPTIONAL. See krige. For local interpolation: only observations within a distance of maxdist from the prediction location are used for prediction or simulation; if combined with nmax, both criteria apply. By default, all observations are used.

ColorRamp

Function defining the colour ramp to be used for plotting the maps OR character representing the colours to be used in the plot. In the latter case, valid values are in: c('Precipitation','Temperature','PCPAnomaly','PCPAnomaly2','TEMPAnomaly','TEMPAno

Logical, indicating if the interpolated values have to be plotted or not

col.nintv

integer, number of colours that have to be used for plotting the interpolated values

Specify at which interpolated values colours change.[MJ m-2 day-1] or [mm d-1] at <-seq(min, max, length.out=col.nintv)</pre>

min <-floor(min(idw["var1.pred"]@data,na.rm=TRUE))</pre> max <-ceiling(max(idw["var1.pred"]@data,na.rm=TRUE))</pre>

main

Character with the title to be used for the plot.

nmin

plot

col.at

stations.plot Logical, indicating if the gauging stations, defined by x.gis have to be plotted stations.offset 2D list with the numeric coordinates in which the label with the amount of gauging stations have to be plotted. e.g., stations.offset = c(450000, 4600000). arrow.plot Logical, indicating if a North Arrow have to be plotted arrow.offset 2D list with the numeric coordinates in which the north arrow has to be plotted. e.g., arrow.offset = c(690000, 4760000)arrow.scale Scale (in the map units) to be used for plotting the north arrow, e.g., scale = 20000 scalebar.plot Logical, indicating if a Scale Bar has to be plotted sb.offset 2D list with the numeric coordinates in which the North Arrow has to be plotted. e.g., sb.offset = c(400000, 4490000)sb.scale Scale (in the map units) to be used for plotting the Scale Bar, e.g., scale = 100000, means that the scale bar will have a length of 100km verbose logical; if TRUE, progress messages are printed allNA.action Action to be executed when all the values in x.ts are NA. Valid values are: -) "error": it will produce an error message. Default option -) a single numeric value that will replace all the NA values in x.ts, giving place to a map with a constant value. At your own risk! dates numeric, factor, or character object indicating how to obtain the ID (usually dates) that will be used to identify the interpolation carried out for each row of If dates is a single number (default), it indicates the index of the column in x.ts that stores the dates If dates is a factor or character vector, its values will be used as ID for the interpolations carried out in each row of x.ts. from Character indicating the starting date for the values stored in all the files that will be read. Character indicating the ending date for the values stored in all the files that will to write2disk Logical. Indicates if we want to write the output into a CSV file. Default value is TRUE out.fmt OPTIONAL, only needed when write2disk==TRUE. Character indicating the type of csv file to be written with the results. Valid values are csv and csv2. For more information, see write.table OPTIONAL. Character with the filename of the output file. Only needed when fname write2disk=TRUE further arguments passed to or from other methods. In particular, these further arguments are passed to the function idw (gstat package) OR autoKrige (automap package), depending on the value passed to formula (see 'details' below): -) for IDW, the arguments are passed to: idw(formula,locations,newdata,nmin,nmax,maxdist,...)

-) for OK, KED, the arguments are passed to: autoKrige(formula,input_data,new_data,nmin,nmax,

Details

The type of interpolation (IDW, OK, KED) is obtained from the argument formula:

-) When formula is missing, an IDW interpolation, by calling the idw function in the **gstat** package, with formula = value~1.

- -) When formula = value $^{-1}$, an OK interpolation, by calling the autoKrige function, with formula = value $^{-1}$.
- -) When formula = value~pred1 + pred2 + ..., a KED interpolation, by calling the autoKrige function, with the formula specified by the user.

When type is block or both, a block interpolation is carried out for each subcatchment defined by subcatchments, so far, computing the average value over all the cells belonging to each subcatchment.

The automatic kriging is carried out by using a variogram generated automatically with the autofitVariogram function of the automap package.

Value

Cells When type is cells, the output object is a SpatialPixelsDataFrame-class, which

slot 'data' has two variables: 'var1.pred' and 'var1.var' with the predictions and

its variances, respectively

Block When type is block, the output object is a SpatialPolygonsDataFrame-class,

which slot 'data' has four variables: 'x', 'y' with the easting and northing coordinate of the centroid of the catchments specified by subcatchments, and 'var1.pred' and 'var1.var' with the predictions and its variances, respectively

list(Cells, Block)

When type is both, the resulting object is a list, with the two elements previously described.

Note

IMPORTANT: It is you responsibility to check the validity of the fitted variogram !!.

hydropairs 47

hydropairs

Visual Correlation Matrix

Description

Visualization of a correlation matrix. On top the (absolute) value of the correlation plus the result of the cor.test as stars. On bottom, the bivariate scatterplots, with a fitted line. On the diagonal, an histogram of each variable.

Usage

```
hydropairs(x, dec = 3, use = "pairwise.complete.obs", method = "pearson",...)
```

Arguments

	umn of x represent values measured at different locations.
dec	decimal places to be used for showing the correlation values
use	See cor. An optional character string giving a method for computing covariances in the presence of missing values. This must be (an abbreviation of) one of the strings "everything", "all.obs", "complete.obs", "na.or.complete", or "pairwise.complete.obs".
method	See cor. A character string indicating which correlation coefficient (or covariance) is to be computed. One of "pearson" (default), "kendall", or "spearman", can be abbreviated
•••	further arguments passed to or from other methods, in particular it is used in the pairs function.

Value

On top the (absolute) value of the correlation plus the result of the cor.test as points
On bottom the bivariate scatterplots, with a fitted line
On diagonal histograms (from pairs)

Note

Original idea taken from the R Graph Gallery (nowadays not available on its original link: http://addictedtor.free.fr/graphiques

Histogram panel was taken from the R help of the original pairs function

## The first column of 'EbroPPtsMonthly' has the dates.
hydropairs(EbroPPtsMonthly[,2:4])
```

hydroplot

Hydrological time series plotting and extraction.

Description

hydroplot: When x is a zoo object it plots (a maximum of) 9 graphs (lines plot, boxplots and/or histograms) of the daily, monthly, annual and/or seasonal time series.

sname2plot: When x is a data frame whose columns contain the time series of several gauging stations, it takes the name of one gauging station and plots the graphs described above.

Usage

```
xlab="Time", ylab=NULL, win.len1=0, win.len2=0,
tick.tstep="auto", lab.tstep="auto", lab.fmt=NULL,
cex=0.3, cex.main=1.3, cex.lab=1.3, cex.axis=1.3,
col=c("blue", "lightblue", "lightblue"),
dates=1, date.fmt = "%Y-%m-%d", from, to, stype="default",
season.names=c("Winter", "Spring", "Summer", "Autumn"),
h=NULL )
```

Arguments

Х

zoo, xts or data.frame object, with columns storing the time series of one or more gauging stations.

sname

ONLY required when x is a data frame.

Character representing the name of a station, which have to correspond to one column name in x

FUN

ONLY required when var. type is missing AND pfreq != "o".

Function that have to be applied for transforming from daily to monthly or annual time step (e.g., For precipitation FUN=sum and for temperature and flow ts, FUN=mean)

na.rm

Logical. Should missing values be removed before the computations?

ptype

Character indicating the type of plot that will be plotted. Valid values are:

- -) ts => only time series
- -) ts+boxplot => only time series + boxplot
- -) ts+hist => only time series + histogram
- -) ts+boxplot+hist => time series + boxplot + histogram

pfreq

Character indicating how many plots are desired by the user. Valid values are:

- -) dma: Daily, Monthly and Annual values are plotted
- -) dm: Daily and Monthly values are plotted
- -) ma: Monthly and Annual values are plotted
- -) o: Only the original zoo object is plotted, and ptype is changed to ts
- -) seasonal: Line and bloxplots of seasonal time series (see stype and season.names). When pfreq is seasonal, ptype is set to ts+boxplot

var.type

ONLY required when FUN is missing.

character representing the type of variable being plotted. Used for determining the function used for computing the monthly and annual values when FUN is missing. Valid values are:

- -) Precipitation => FUN=sum
- -) Temperature => FUN=mean
- -) Flow => FUN=mean

var.unit

Character representing the measurement unit of the variable being plotted. ONLY used for labelling the axes (e.g., "mm" for precipitation, "C" for temperature, and "m3/s" for flow.)

main

Character representing the main title of the plot. If the user do not provide a title, this is created automatically as: main= paste(var.type, "at", sname, sep=""),

xlab	A title for the x axis. See plot.
ylab	A title for the y axis. See plot.
win.len1	number of days for being used in the computation of the first moving average. A value equal to zero indicates that this moving average is not going to be computed.
win.len2	number of days for being used in the computation of the second moving average. A value equal to zero indicates that this moving average is not going to be computed.
tick.tstep	Character indicating the time step that have to be used for putting the ticks on the time axis. Valid values are: -) days, -) months, -) years
lab.tstep	Character indicating the time step that have to be used for putting the labels on the time axis. Valid values are: -) days, -) months, -) years
lab.fmt	Character indicating with the format to be used for the label of the axis. See format in as.Date. If not specified, it will try "%Y-%m-%d" when lab.tstep=="days", "%b" when lab.tstep=="month", and "%Y" when lab.tstep=="year".
cex	A numerical value giving the amount by which plotting text and symbols should be magnified relative to the default. (See par).
cex.main	The magnification to be used for main titles relative to the current setting of cex (See par).
cex.lab	The magnification to be used for x and y labels relative to the current setting of cex (See par).
cex.axis	The magnification to be used for axis annotation relative to the current setting of cex (See par).
col	A character vector with 3 elements, representing the colors to be used for plotting the lines of the ts, the boxplots, and the histograms, respectively. When pfreq="o", only one character element is needed. See plot.default).
dates	ONLY required when x is a data frame. It is a numeric, factor or Date object indicating how to obtain the dates corresponding to the sname station. If dates is a number (default), it indicates the index of the column in x that stores the dates If dates is a factor, it is converted into Date class, using the date format specified by date. fmt If dates is already of Date class, the code verifies that the number of days in dates be equal to the number of element in x
date.fmt	Character indicating the format in which the dates are stored in <i>dates</i> , <i>from</i> and <i>to</i> . See format in as.Date. ONLY required when class(dates)=="factor" or class(dates)=="numeric".

from OPTIONAL, used for extracting a subset of values. Character indicating the starting date for the values to be extracted. It must be provided in the format specified by date.fmt. OPTIONAL, used for extracting a subset of values. to Character indicating the ending date for the values to be extracted. It must be provided in the format specified by date. fmt. OPTIONAL, only used when pfreq=seasonal. stype character, indicating which weather seasons will be used for computing the output. Possible values are: -) default => "winter"= DJF = Dec, Jan, Feb; "spring"= MAM = Mar, Apr, May; "summer"= JJA = Jun, Jul, Aug; "autumn"= SON = Sep, Oct, Nov -) FrenchPolynesia => "winter"= DJFM = Dec, Jan, Feb, Mar; "spring"= AM = Apr, May; "summer"= JJAS = Jun, Jul, Aug, Sep; "autumn"= ON = Oct, Nov OPTIONAL, only used when pfreq=seasonal. season.names character of length 4 indicating the names of each one of the weather seasons defined by stype. These names are only used for plotting purposes h OPTIONAL, only used when pfreq=seasonal, for plotting horizontal lines in each seasonal plot. numeric, with 1 or 4 elements, with the value used for plotting an horizontal line in each seasonal plot, in the following order: winter (DJF), spring (MAM), summer (JJA), autumn (SON). further arguments passed to the plot.zoo and axis functions or from other . . .

Details

Plots of the daily/monthly/annual/seasonal values of the time series given as input.

Depending on the value of pfreq, daily, monthly, annual and/or seasonal time series plots, boxplots and histograms are produced.

Depending on the value of ptype, time series plots, boxplots and/or histograms are produced.

hypsometric

Hypsometric Curve

Description

Computes and plots the hypsometric curve corresponding to the data provided by a digital elevation model (DEM)

Usage

```
hypsometric(x, band=1, main="Hypsometric Curve",
xlab="Relative Area above Elevation, (a/A)",
ylab="Relative Elevation, (h/H)", col="blue",...)
```

Arguments

Х

SpatialGridDataFrame-class object with the elevations of the catchment. Possibly, a raster file already read with the readGDAL function of the **rgdal** package.

hypsometric 53

band	integer or character indicating the band in x that stores the elevation data.
main	See plot. An overall title for the plot: see title.
xlab	See plot. A title for the x axis: see title.
ylab	See plot. A title for the y axis: see title.
col	See plot.default. The colors for lines and points.
	further arguments passed to or from other methods

Details

The hypsometric curve and the hypsometric integral are non-dimensional measures of the proportion of the catchment above a given elevation.

Strahler (1952, 1964) further asserted that different types of landform have different characteristic shape of their hypsometric curves, dividing landforms into 'young' and 'mature' with decreasing hypsometric integral -the area under the hypsometric curve- with age.

infillxy

Infills NA values

Description

Infill all the missing values (NA) in x with the corresponding values in sim.

Usage

```
infillxy(x, ...)
## Default S3 method:
infillxy(x, sim, ...)
## S3 method for class 'matrix'
infillxy(x, sim, ...)
## S3 method for class 'data.frame'
infillxy(x, sim, ...)
```

Arguments

x numeric, data.frame or matrix in which some values are missing (NA).

sim numeric, data.frame or matrix, with the same dimension of x, which contains the values that will be used for infilling the missing (NA) values in x

... further arguments passed to or from other methods.

Details

It gives as a result an object of the same dimension of x, in which all the NA values were infilled with the corresponding values of sim.

Author(s)

Mauricio Zambrano-Bigiarini, <mzb.devel@gmail>

istdx 55

Examples

```
obs <- c(1, NA, 3, 4, NA, 5)
sim <- rep(2, 6)
## Filling in the missing values in 'x' with the corresponding values in 'sim'
infillxy(x=obs, sim)</pre>
```

istdx

Inverse Standarization

Description

This function back transforms a standarized vector/matrix z into their original values, i.e., re-scales all the values in the [0,1] interval to the original range of values z = re-scale(x) = x*[xmax - xmin] + xmin.

Usage

```
istdx(x, ...)
## Default S3 method:
istdx(x, xmin, xrange, ...)
```

Arguments

x standarized vector or matrix to be re-scaled, all the values have to be in the range

[0,1]

xmin numeric with the minimum value(s) in the original x

-) if x is a vector, xmin has to be a real

-) if x is a matrix/data.frame, xmin has to be a vector, with the minimum values for each column of the original x. In this case, the vector of minimums can be

obtained as: xmin <-apply(x,2,min,na.rm=TRUE)

xrange numeric with the range of value(s) in the original x

-) if x is a vector, xrange has to be a real

-) if x is a matrix/data.frame, xrange has to be a vector, with the range of values for each column of the original x. In this case, the vector of ranges can be

obtained as:

xrange <-apply(x,2,range,na.rm=TRUE)
xrange <-apply(xrange,2,diff,na.rm=TRUE)</pre>

... further arguments passed to or from other methods

izoo2rzoo

Irregular Zoo -> Regular Zoo

Description

It takes an irregular zoo object (with non-existing values for some dates) and converts it into a regularly spaced zoo object within the time period defined by from and to, by filling the missing dates with 'NA'

izoo2rzoo 57

Usage

```
izoo2rzoo(x, ...)
## Default S3 method:
izoo2rzoo(x, from= start(x), to= end(x), date.fmt= "%Y-%m-%d", tstep= "days", ...)
## S3 method for class 'zoo'
izoo2rzoo(x, from= start(x), to= end(x), date.fmt= "%Y-%m-%d", tstep= "days", ...)
```

Arguments

X	irregular zoo object (vector or matrix) representing a time series (very likely read with some user-defined procedure, and with some missing values for particular days/months/years)
from	Character indicating the starting date for creating the regularly spaced zoo object. The default value corresponds to the date of the first element of x It has to be in the format indicated by date.fmt.
to	Character indicating the ending date for creating the regularly spaced zoo object. The default value corresponds to the date of the last element of x It has to be in the format indicated by date.fmt.
date.fmt	character indicating the format in which the dates are stored in from and to, e.g. %Y-%m-%d. See 'Details' section in strptime
tstep	character, indicating the time step used for creating the time sequence going from from to to that will be used as time(x) Valid values are (but not limited to) days, months, years, hours
	further arguments passed to or from other methods

Details

If the full time period of x is a subset of the time period defined by from and to, the time period of the resulting zoo is the one defined by from and to, assigning 'NA' to all the dates in which x do not have a value.

Value

a regularly spaced zoo object, with values given by x and time stamps going from from to to at intervals defined by tsteps

## Example 3: Working with a zoo matrix
Y \leftarrow cbind(x,x)
# Adding a missing value (NA in this case) for Feb 29th in all the columns of Y
rY <- izoo2rzoo(Y, from="1964-02-25", to="1964-03-05")
## Example 4: Working with hourly data, from 01:00 to 10:00 on 12th December 2000
dates <- ISOdatetime(2000, 12, 12, 1:10, 0, 0)
values <- 1:10
       <- zoo(values, dates)
# removing values from 02:00 to 05:00 (not present at all in 'x', not even NA !)
x <- x[-c(2:5)]
\# Adding missing values (NA in this case) from 02:00 to 05:00
y <- izoo2rzoo(x, date.fmt="%Y-%m-%d %H:%M:%S", tstep="hours")
```

ma 59

Description

Time series with hourly streamflows for the Karamea River(New Zeland) measured at the gauging station "Gorge", for the period 01/Jan/1980 to 31/Dec/1985. Station Number: 95102, Easting Coordinate (NZMG): 2444629.0, Northing Coordinate (NZMG): 5994427.0, Catchment Area (km2): 1160.0.

Usage

```
data(KarameaAtGorgeQts)
```

Format

zoo object.

Source

These data are intended to be used for research purposes only, being distributed in the hope that it will be useful, but WITHOUT ANY WARRANTY.

ma

Moving Average

Description

Generic function for computing a moving (sliding) average of ts.

Usage

```
ma(x, ...)
## Default S3 method:
ma(x, win.len, FUN = mean, ...)
## S3 method for class 'zoo'
ma(x, win.len, FUN = mean, ...)
```

Arguments

x ts or zoo object.

win.len number of terms that will be considered in the mean. It have to be odd

FUN Function that have to be applied for computing the moving average. Usually,

FUN MUST be mean

further arguments passed to or from other methods.

60 Maquehue Temuco

Value

a vector with the moving average terms. The length of the resulting vector is the same of x, but the first and last (win.len-1)/2 elements will be NA.

Author(s)

Mauricio Zambrano-Bigiarini, <mzb.devel@gmail>

Examples

```
## Loading daily streamflows at the station Oca en Ona (Ebro River basin, Spain) ##
data(OcaEnOnaQts)
x <- OcaEnOnaQts

## Daily to Monthly ts
m <- daily2monthly(x, FUN=mean, na.rm=FALSE)

# Plotting the monthly values
plot(m, xlab="Time")

## Plotting the annual moving average in station 'x'
lines(ma(m, win.len=12), col="blue")</pre>
```

MaquehueTemuco

San Martino, ts of daily precipitation.

Description

Daily time series of precipitation, maximum and minimun air temperature at station Maquehue Temuco Ad. (DMC_ID:380013), Araucania Region, Chile (Lat:-38.770, Lon:-72.637), with data from 01/Jan/1950 to 31/Dec/2015 (including some gaps).

Usage

```
data(MaquehueTemuco)
```

Format

zoo matrix with 3 columns:

- -) *pcp*: daily precipitation, [mm/day].
- -) tmx: daily maximum air temperature, [degree Celsius].
- -) tmn: daily minimum air temperature, [degree Celsius].

matrixplot 61

Source

matrixplot Matrixplot

Description

Plots a color matrix, representing the values stored in x.

Originally, it was thought to represent the amount of days with information per year in a set of gauging stations, but it can be used for plotting the information stored in any two dimensional matrix.

Usage

```
matrixplot(x, ColorRamp="Days", ncolors = 70, main = "", ...)
```

Arguments

matrix to be plotted. Originally: Х -) Each column of x represent a different gauging station, and it stores the values measured on it -) Each row of x represent the years, and they stores the amount of days with information in each station ColorRamp Character or function defining a personalized color ramp for plotting the maps. Valid character values are in c("Days", "Precipitation", "Temperature", "PCPAnomaly", "PCPAnomaly2" "TEMPAnomaly", "TEMPAnomaly2", "TEMPAnomaly3"). ncolors numeric, indicating the number of color intervals that will be used for representing the information content of x. Main title for the plot main further arguments passed to levelplot function (lattice package) or from other methods

Examples

mip

Months in Period

Description

Given any starting and ending dates, it generates:

- 1) a vector of class 'Date' with all the months between the two dates (both of them included), OR
- 2) the amount of months between the two dates

Usage

```
mip(from, to, date.fmt = "%Y-%m-%d", out.type = "seq")
```

Arguments

from	Character indicating the starting date for creating the sequence. It has to be in the format indicated by date.fmt.
to	Character indicating the ending date for creating the sequence. It has to be in the format indicated by date.fmt.
date.fmt	Character indicating the format in which the dates are stored in from and to, e.g. %Y-%m-%d. See format in as.Date.

monthlyfunction 63

out.type

character indicating the type of result that is given by this function. Valid values are:

- -) seq: a vectorial sequence with all the months within the given year
- -) nmbr: the number of days in the vectorial sequence with all the months within the given year

Value

Depending on the value of out. type, it returns:

- 1) a vector of class Date with all the months between from and to (both of them included), OR
- 2) a single numeric value with the amount of months between the two dates.

# Sequence of monthly dates between "1961-01-01" and "1961-12-31" ## mip("1961-01-01", "1961-12-31")

## Computing the number of months between "1961-01-01" and "1965-06-30", ## with the date format "%d-%m-%Y" ## mip("01-01-1961", "30-06-1965", date.fmt= "%d-%m-%Y", out.type = "nmbr")
```

monthlyfunction

Monthly Function

Description

Generic function for obtaining 12 monthly values of a zoo object, by applying any R function to ALL the values in the object belonging to each one of the 12 calendar months (Jan...Dec).

Usage

```
monthlyfunction(x, ...)
## Default S3 method:
monthlyfunction(x, FUN, na.rm = TRUE, ...)
## S3 method for class 'zoo'
monthlyfunction(x, FUN, na.rm=TRUE,...)
```

64 monthlyfunction

```
## S3 method for class 'data.frame'
monthlyfunction(x, FUN, na.rm = TRUE, dates=1,
       date.fmt = "%Y-%m-%d", out.type = "data.frame", verbose = TRUE, ...)
## S3 method for class 'matrix'
monthlyfunction(x, FUN, na.rm = TRUE, dates=1,
       date.fmt = "%Y-%m-%d", out.type = "data.frame", verbose = TRUE, ...)
```

Arguments

zoo, xts, data.frame or matrix object, with daily or monthly time series. Х

> Measurements at several gauging stations can be stored in a data.frame of matrix object, and in that case, each column of x represent the time series measured in each gauging station, and the column names of x have to correspond to the ID

of each station (starting by a letter).

Function that will be applied to ALL the values in x belonging to each one of

the 12 months of the year (e.g., FUN can be some of mean, sum, max, min, sd).

Logical. Should missing values be removed? na.rm

> -) TRUE : the monthly values and FUN are computed considering only those values in x different from NA

> -) FALSE: if there is AT LEAST one NA within a month, the corresponding monthly value will be NA

dates It is only used when x is not a zoo object.

numeric, factor, Date indicating how to obtain the dates.

If dates is a number (default), it indicates the index of the column in x that stores the dates

If dates is a factor, it is converted into 'Date' class, using the date format specified by date.fmt

If dates is already of Date class, the code verifies that the number of days in dates be equal to the number of elements in x

date.fmt It is only used when x is not a zoo object.

> character indicating the format in which the dates are stored in dates, e.g. %Y-%m-%d. See format in as. Date.

ONLY required when class(dates)=="factor" or class(dates)=="numeric".

It is only used when x is a matrix or data.frame. out.type

Character defining the desired type of output. Valid values are:

-) data.frame: a data.frame, with 12 columns representing the months, and as many rows as gauging stations are included in x

-) db: a data.frame, with 4 columns will be produced. Useful for a posterior

The first column ('StationID') will store the ID of the station,

The second column ('Year') will store the year, The third column ('Month') will store month,

The fourth column ('Value') will contain the monthly value corresponding to the three previous columns.

Logical; if TRUE, progress messages are printed verbose

further arguments passed to or from other methods

FUN

monthlyfunction 65

Value

When x is a zoo object, a numeric vector with 12 elements representing the computed monthly value for each month.

When x is a data.frame which columns represent measurements at different gauging stations, the resulting object is a data.frame with 12 columns and as many rows as gauging stations are in x, each row storing the computed 12 monthly value for each gauging station.

Note

Due to the fact that FUN is applied over all the elements in x belonging to a given calendar month, its result will depend on the sampling frequency of x and the type of function provided by FUN (**special attention have to be put when** FUN=sum)

```

mspplot

Multiple spplot

Description

Plots several spatial maps in the same plotting window, with options to easily add a scale bar and north arrow.

Originally, it was though to make easier the display of several maps (of the same spatial extent) obtained by different interpolation methods or for different time steps.

Usage

```
mspplot(x, subcatchments, IDvar = NULL, p4s=CRS(as.character(NA)),
    plot = TRUE, ColorRamp="PCPAnomaly",col.nintv = 10, col.at = "auto",
    main, stations.plot = FALSE, stations.gis, X, Y,
    arrow.plot = FALSE, arrow.offset, arrow.scale,
    scalebar.plot = FALSE, sb.offset, sb.scale, verbose = TRUE)
```

Arguments

guments		
X	SpatialPixelsDataFrame-class object that stores (in the @data slot) all the maps that will be plotted.	
subcatchments	SpatialPolygonsDataFrame-class with all the subcatchments within the study area, OR character representing the filename (with path) of the shapefile ('polygon' type) that stores those subcatchments.	
IDvar	See readShapePoly. Character string with the name of a column in the subcatchments shapefile DBF containing the ID values of the catchments - the values will be converted to a character vector.	
p4s	Character with information about the projection of the GIS files, usually created by the CRS function of the sp package	
plot	Logical, indicating if the interpolated values have to be plotted or not	
ColorRamp	Character or function defining a personalized color ramp for plotting the maps. Valid character values are in c("Precipitation", "Temperature", "PCPAnomaly", "PCPAnomaly2" "TEMPAnomaly2", "TEMPAnomaly3").	
col.nintv	integer, number of colors that have to be used for plotting the interpolated values	
col.at	Specify at which interpolated values colours change. Valid values are: -) R: uses the default setting of 'spplot' -) auto: default option. at <-seq(min,max,length.out=col.nintv) min <-floor(min(idw["var1.pred"]@data,na.rm=TRUE)) max <-ceiling(max(idw["var1.pred"]@data,na.rm=TRUE)) -) numeric: vector giving the exact values in which the colors have to change. Useful when the user desires the same color for the same value when comparing two or more maps with different range of values	
main	Character with the title to be used for the plot	
stations.plot	Logical, indicating if the gauging stations, defined by stations.gis have to be plotted	
stations.gis	OPTIONAL. data.frame with the stations that will be added to the plot. ONLY required when stations.plot == TRUE.	
X	OPTIONAL. character, field name in $x.gis$ that stores the easting coordinate of the stations. ONLY required when stations.plot == TRUE.	
Υ	OPTIONAL. character, field name in $x.gis$ that stores the northing coordinate of the stations. ONLY required when stations.plot == TRUE.	
arrow.plot	Logical, indicating if a North Arrow have to be plotted	
arrow.offset	OPTIONAL. 2D list with the numeric coordinates in which the North Arrow have to be plotted. e.g., arrow.offset = c(690000, 4760000). ONLY required	

when arrow.plot=TRUE

arrow.scale OPTIONAL. Scale (in the map units) to be used for plotting the North Arrow,

e.g., scale = 20000. ONLY required when arrow.plot=TRUE.

scalebar.plot Logical, indicating if a Scale Bar have to be plotted

sb.offset OPTIONAL. 2D list with the numeric coordinates in which the North Arrow

have to be plotted. e.g., sb. offset = c(400000,4490000). ONLY required

when scalebar.plot=TRUE

sb. scale OPTIONAL. Scale (in the map units) to be used for plotting the Scale Bar, e.g.,

scale = 100000, means that the scale bar will have a length of 100km. ONLY

required when scalebar.plot=TRUE.

verbose logical; if TRUE, progress messages are printed

OcaEnOnaQts

Oca in "Ona" (Q0931), time series of daily streamflows.

Description

Time series with daily streamflows of the Oca River (subcatchment of the Ebro River basin, Spain) measured at the gauging station "Ona" (Q093), for the period 01/Jan/1961 to 31/Dic/1963

Usage

```
data(OcaEnOnaQts)
```

Format

zoo object.

Source

Downloaded from the web site of the Confederacion Hidrografica del Ebro (CHE) http://www.chebro.es/ (original link http://oph.chebro.es/documentacion/CaudalEA/CaudalEA.htm, last accessed [March 2010]).

These data are intended to be used for research purposes only, being distributed in the hope that it will be useful, but WITHOUT ANY WARRANTY.

rm1stchar

Remove First Character(s)

Description

Deletes the first n character(s) of a character object.

Usage

```
rm1stchar(x, n = 1)
```

Arguments

x Character, e.g., each element may represent the name of a single gauging station.

n numeric, indicating the number of characters that have to be removed from the beginning of x

SanMartinoPPts 71

Value

character object of the same length as x.

72 seasonalfunction

seasonalfunction

Seasonal Function

Description

Generic function for applying any R function to a zoo object, in order to obtain 4 representative seasonal values.

Usage

```
seasonalfunction(x, ...)
## Default S3 method:
seasonalfunction(x, FUN, na.rm = TRUE, type="default", ...)
## S3 method for class 'zoo'
seasonalfunction(x, FUN, na.rm = TRUE, type="default", ...)
## S3 method for class 'data.frame'
seasonalfunction(x, FUN, na.rm = TRUE, type="default",
                          dates=1, date.fmt = "%Y-%m-%d",
                          out.type = "data.frame", verbose = TRUE, ...)
## S3 method for class 'matrix'
seasonalfunction(x, FUN, na.rm = TRUE, type="default",
                          dates=1, date.fmt = "%Y-%m-%d"
                          out.type = "data.frame", verbose = TRUE, ...)
```

Arguments

zoo, data.frame or matrix object, with daily or monthly time series.

Measurements at several gauging stations can be stored in a data.frame of matrix object, and in that case, each column of x represent the time series measured in each gauging station, and the column names of x have to correspond to the ID

of each station (starting by a letter).

FUN

Function that will be applied to ALL the values in x belonging to each one of the 4 weather seasons (e.g., FUN can be some of mean, max, min, sd).

na.rm

Logical. Should missing values be removed before the computations?

-) TRUE: the monthly values are computed considering only those values in x different from NA (very important when FUN=sum)

-) FALSE: if there is AT LEAST one NA within a month, the FUN and monthly values are NA

type

character, indicating which weather seasons will be used for computing the output. Possible values are:

-) default => "winter" = Dec, Jan, Feb; "spring" = Mar, Apr, May; "summer" = Jun,

seasonal function 73

Jul, Aug; "autumn"= Sep, Oct, Nov

-) FrenchPolynesia => "winter"= Dec, Jan, Feb, Mar; "spring"= Apr, May; "summer"=Jun, Jul, Aug, Sep; "autumn"= Oct, Nov

dates numeric, factor, Date indicating how to obtain the dates.

If dates is a number (default), it indicates the index of the column in x that stores the dates

If dates is a factor, it is converted into Date class, by using the date format specified by date.fmt

If dates is already of Date class, the code verifies that the number of days in dates be equal to the number of element in x

date.fmt Character indicating the format in which the dates are stored in dates, e.g.

Y-m-%d. See format in as.Date.

ONLY required when class(dates)=="factor" or class(dates)=="numeric".

out.type Character defining the desired type of output. Valid values are:

-) data.frame: a data.frame, with 4 columns representing the weather seasons, and as many rows as stations are included in x

-) db: a data.frame, with 4 colums will be produced. Useful for a posterior boxplot

The first column (StationID) will store the ID of the station,

The second column (Year) will store the year, The third column (Season) will store the season,

The fourth column (Value) will contain the seasonal value corresponding to that

year and that station.

verbose Logical; if TRUE, progress messages are printed
... further arguments passed to or from other methods

Warning

The *FUN* value for the winter season (DJF) is computed considering the consecutive months of December, January and February. Therefore, if x starts in January and ends in December of any year, the winter value of the first year is computed considering only the January and February value of that year, whereas the December value of the first year is used to compute the winter value of the next year.

Note

FUN is applied to all the values of x belonging to each one of the four weather seasons, so the results of this function depends on the frequency sampling of x and the type of function given by FUN

# Mean autumn (SON) value
sum( extractzoo(x, trgt="SON") ) / nyears
```

sfreq

Sampling Frequency

Description

This function identifies the sampling frequency of a zoo object. So far, it only works with daily/monthly/annual ts.

Usage

```
sfreq(x, min.year = 1800)
```

Arguments

x variable of type zoo, xts or ts, with AT LEAST 2 elements, AND with a daily,

monthly or annual sampling frequency.

min.year integer used for a correct identification of the sampling frequency when x is an

annual time series.

smry 75

Value

Character. Possible values are:

-) daily: indicating that the sampling frequency in x is daily

-) monthly: indicating that the sampling frequency in x is monthly

-) annual: indicating that the sampling frequency in x is annual

smry

Summary

Description

Extended summary function for numeric objects, with 13 summary statistics.

76 smry

Usage

```
smry(x, ...)
## Default S3 method:
smry(x, na.rm=TRUE, digits = max(3, getOption("digits")-3), ...)
## S3 method for class 'zoo'
smry(x, na.rm=TRUE, digits = max(3, getOption("digits")-3), ...)
## S3 method for class 'Date'
smry(x, na.rm=TRUE, digits = max(3, getOption("digits")-3), ...)
## S3 method for class 'matrix'
smry(x, na.rm=TRUE, digits = max(3, getOption("digits")-3), ...)
## S3 method for class 'data.frame'
smry(x, na.rm=TRUE, digits = max(3, getOption("digits")-3), ...)
```

Arguments

X	a numeric object, vector, matrix or data.frame, for which a summary is desired.
na.rm	a logical value indicating whether 'NA' values should be stripped before the computation proceeds.
digits	numeric, with the amount of decimal places to be included in the result
	further arguments passed to or from other methods.

Value

Computed summary statistics are:

Min	Minimum
1stQ	First quartile (lower-hinge)
Mean	Mean value
Median	Median
3rdQ	Third quartile (upper-hinge
Max	Maximum of the input values.
IQR	Interquartile Range. $IQR(x) = quantile(x,3/4) - quantile(x,1/4)$
sd	Standard deviation. It uses 'n-1' as denominator.
cv	Coefficient of variation (cv= sd / mean)
skewness	Skewness (using e1071 package)
kurtosis	Kurtosis (using e1071 package)
n	Total number of elements
NA's	Amount of missing values

sname2ts 77

Note

Skewness and Kurtosis are computed with the e1071 package

sname2ts

Station Name -> Time Series

Description

This function takes a data frame whose columns contains the time series of several gauging stations, along with a character representing the name of one gauging station, and extracts the time series corresponding to that station.

Usage

Arguments

x data.frame containing the complete times series of all the stations.

It may also contain 1 column with the dates of the measurements, or they can be

provided in a different way (see dates below).

sname Character representing the name of a station, which have to correspond to one

column name in x

dates numeric, factor, Date object indicating how to obtain the dates corresponding to

the sname station.

-) If dates is a number (default), it indicates the index of the column in x that

- stores the dates
- -) If dates is a factor, it is converted into Date class, using the date format specified by date.fmt
- -) If dates is already of Date class, the code verifies that the number of days in dates be equal to the number of element in \boldsymbol{x}

78 sname2ts

date.fmt character indicating the format in which the dates are stored in *dates*, e.g. %Y-%m-%d.

See format in as.Date.

ONLY required when class(dates)=="factor" or class(dates)=="numeric".

var.type character representing the type of variable being plotted. Used for determining

the function used for computing the monthly or/and annual values when FUN is missing. Valid values are:

-) Precipitation => FUN=sum

-) Temperature => FUN= mean

-) Flow => FUN= mean

tstep.out character that defines the time step of the desired output time series. Valid values

are:

-) daily : daily time series-) monthly: monthly time series-) annual : annual time series

FUN ONLY required when var.type is missing and tstep is one of monthly or

annual.

Function that have to be applied for transforming from daily to monthly or annual time step (e.g., for precipitation FUN=sum and for temperature and flow ts,

FUN=mean)

na.rm a logical value indicating whether 'NA' values should be stripped before the

computation proceeds.

from OPTIONAL, used for extracting a subset of values.

Character indicating the starting date for the values to be extracted. It must be

provided in the format specified by date.fmt.

to OPTIONAL, used for extracting a subset of values.

Character indicating the ending date for the values to be extracted. It must be

provided in the format specified by date.fmt.

80 subdaily2daily

subdaily2daily

Sub-daily -> Daily

Description

Generic function for transforming a Sub-DAILY time series into a DAILY one

Usage

```
subdaily2daily(x, ...)
## Default S3 method:
subdaily2daily(x, FUN, na.rm = TRUE, start="00:00:00", ...)
## S3 method for class 'zoo'
subdaily2daily(x, FUN, na.rm = TRUE, start="00:00:00", ...)
## S3 method for class 'data.frame'
subdaily2daily(x, FUN, na.rm = TRUE, start="00:00:00",
           dates=1, date.fmt="%Y-%m-%d %H:%M:%S", out.fmt="zoo",
           verbose= TRUE, ...)
## S3 method for class 'matrix'
subdaily2daily(x, FUN, na.rm = TRUE, start="00:00:00",
           dates=1, date.fmt="%Y-%m-%d %H:%M:%S", out.fmt="zoo",
           verbose= TRUE, ...)
```

Arguments

xts, data.frame or matrix object, with sub-daily time series. Χ

> Measurements at several gauging stations can be stored in a data.frame or matrix object, and in that case, each column of x represent the time series measured in each gauging station, and the column names of x should correspond to the ID of

each station (starting by a letter).

FUN Function that have to be applied for transforming from sub-daily to daily time

step. (e.g., for precipitation FUN=sum and for temperature and streamflow ts,

FUN=mean).

Logical. Should missing values be removed? na.rm

> -) TRUE: the daily values are computed considering only those values different from NA

> -) FALSE: if there is AT LEAST one NA sub-daily value within a day, the corresponing daily value(s) will be NA as well

character, indicating the starting time used for aggregating subdaily time series into daily ones. It MUST be provided in the "%H:%M:%S" format.

start

time2season 81

dates	numeric, factor, POSIXct or POSIXt object indicating how to obtain the dates and times for each gauging station If dates is a number, it indicates the index of the column in x that stores the date and times If dates is a factor, it is converted into POSIXct class, using the date format specified by date. fmt If dates is already of POSIXct or POSIXt class, the code verifies that the number of elements on it be equal to the number of elements in x
date.fmt	character indicating the format in which the dates are stored in dates, By default date.fmt=%Y-%m-%d %H:%M:%S. See format in as.Date. ONLY required when class(dates)=="factor" or class(dates)=="numeric".
out.fmt	OPTIONAL. Only used when x is a matrix or data.frame object /cr character, for selecting if the result will be a matrix/data.frame or a zoo object. Valid values are: numeric, zoo (default)
verbose	logical; if TRUE, progress messages are printed
	further arguments passed to or from other methods.

data(KarameaAtGorgeQts)
x <- KarameaAtGorgeQts

# Plotting the hourly streamflow values
plot(x)

## sub-daily to Daily
d <- subdaily2daily(x, FUN=sum, na.rm=TRUE)

# Plotting the daily streamflow values
plot(d)</pre>
```

time2season

Date/DateTime character -> Seasonal character

82 time2season

Description

This function transforms a character vector of Dates or DateTimes into a character vector of seasons (summer, winter, autumn, spring), depending on the value of type:

```
When type=default -) winter = DJF: December, January, February
```

- -) spring = MAM: March, April, May
- -) summer = JJA: June, July, August
- -) autumn = SON: September, October, November

When type=FrenchPolynesia -) winter = DJFM: December, January, February, March

- -) spring = AM : April, May
- -) summer = JJAS: June, July, August, September
- -) autumn = ON: October, November

Usage

```
time2season(x, out.fmt = "months", type="default")
```

Arguments

vector with the dates that have to be transformed. class(x) must be Date
out.fmt character, indicating the format of the output seasons. Possible values are:
-) seasons => c("winter", "spring", "summer", autumn")
-) months => c("DJF", "MAM", "JJA", SON") or c("DJFM", "AM", "JJAS", ON")

type

character, indicating which weather seasons will be used for computing the output. Possible values are:
-) default => "winter"= Dec, Jan, Feb; "spring"= Mar, Apr, May; "summer"=Jun, Jul, Aug; "autumn"= Sep, Oct, Nov
-) FrenchPolynesia => "winter"= Dec, Jan, Feb, Mar; "spring"= Apr, May; "summer"=Jun, Jul, Aug, Sep; "autumn"= Oct, Nov

Value

character vector with the weather season to which each date in x belongs

Note

Weather seasons corresponding to French Polynesia were defined following a comment from Lydie Sichoix

## Sequence of daily dates between "1961-01-01" and "1961-12-31"
t <- dip("1961-01-01", "1961-12-31")
time2season(t)

## Sequence of monthly dates between "1961-01-01" and "1961-12-31"
t <- mip("1961-01-01", "1961-12-31")
time2season(t)
time2season(t, out.fmt="seasons")</pre>
```

vector2zoo

Vector -> Zoo

Description

Transform a numeric vector and its corresponding dates into a zoo object.

Usage

```
vector2zoo(x, dates, date.fmt = "%Y-%m-%d")
```

Arguments

Χ	numeric vector
dates	character, factor, Date or POSIXct object with the dates corresponding to each element of x. Valid object class for dates are: character, factor, Date, POSIXct
date.fmt	character indicating the format in which the dates are stored in <i>dates</i> , e.g. %Y-%m-%d. See 'Details' section in strptime. ONLY required when class(dates)=="factor" or class(dates)=="character".

Value

a zoo object, with values given by x and time stamps given by dates

Author(s)

Mauricio Zambrano-Bigiarini, <mzb.devel@gmail>

```

84 yip

Examples

```
##
## Example1: creating daily data
# Generating a numeric variable (e.g., read from the outputs of an hydrological model)
x <- 1:31
# Generating the dates corresponding to the previous values
dates <- dip("1961-01-01", "1961-01-31")

## Transforming from 'numeric' to 'zoo' class
z <- vector2zoo(x, dates)

##
## Example2: creating hourly data
# Generating a numeric variable
x <- rnorm(7)
# Generating hourly times since 17:00:00 up to 23:00:00 for 2012-Oct-15
dates <- ISOdatetime(2012, 10, 15, 17:23, 00, 0)

## Transforming from 'numeric' to 'zoo' class
z <- vector2zoo(x, dates)</pre>
```

yip

Years in Period

Description

Given any starting and ending dates, it generates:

- 1) a vector of class Date with all the years between the two dates (both of them included), OR
- 2) the amount of years between the two dates

Usage

```
yip(from, to, date.fmt = "%Y-%m-%d", out.type = "seq")
```

Arguments

from	Character indicating the starting date for creating the sequence. It has to be in the format indicated by date.fmt.
to	Character indicating the ending date for creating the sequence. It has to be in the format indicated by date.fmt.
date.fmt	character indicating the format in which the dates are stored in from and to, e.g. %Y-%m-%d. See format in as Date.

zoo2RHtest 85

out.type

Character indicating the type of result that is given by this function. Valid values are:

- -) seq => a vectorial sequence with all the years within the given dates.
- -) nmbr => the number of years within the given dates.

Value

Depending on the value of out. type, it returns:

- 1) seq: a vector of class Date with all the years between from and to (both of them included), OR
- 2) nmbr: a single numeric value with the amount of years between the two dates.

## by using "%d-%m-%Y" as date format ##

yip("01-01-1961", "01-01-1975", date.fmt= "%d-%m-%Y", out.type = "nmbr")
```

zoo2RHtest

Zoo -> RHTest

Description

It creates the input file to the '*RHtest_dlyPrcp.r*' script, used for testing the homogeneity of climatological time series (available at: http://etccdi.pacificclimate.org/software.shtml)

Usage

```
zoo2RHtest(x, fname="pcp.txt", tstep.out="daily", dec=".", na="-999.0")
```

Arguments

X	time series that will be written. class(x) must be a zoo object
fname	Character, with the filename of the precipitation time series
tstep.out	Character indicating the time step that have to be used for writing \boldsymbol{x} into the output file
dec	the string to use for decimal points in numeric or complex columns: must be a single character.
na	character to be used for representing the missing values in the data
