

# Package ‘ldhmm’

October 13, 2022

**Type** Package

**Title** Hidden Markov Model for Financial Time-Series Based on Lambda Distribution

**Version** 0.5.1

**Date** 2019-12-05

**Author** Stephen H-T. Lihn [aut, cre]

**Maintainer** Stephen H-T. Lihn <stevelihn@gmail.com>

**Description** Hidden Markov Model (HMM) based on symmetric lambda distribution framework is implemented for the study of return time-series in the financial market. Major features in the S&P500 index, such as regime identification, volatility clustering, and anti-correlation between return and volatility, can be extracted from HMM cleanly. Univariate symmetric lambda distribution is essentially a location-scale family of exponential power distribution. Such distribution is suitable for describing highly leptokurtic time series obtained from the financial market. It provides a theoretically solid foundation to explore such data where the normal distribution is not adequate. The HMM implementation follows closely the book: “Hidden Markov Models for Time Series”, by Zucchini, MacDonald, Langrock (2016).

ldhmm-package	<i>ldhmm: A package for HMM using lambda distribution.</i>
---------------	--

---

## Description

The `ldhmm` package provides the core class and functions to calculate Hidden Markov Model (HMM) using lambda distribution framework. The main goal is to provide a theoretically solid foundation to explore the return time-series in the financial market, where the normal distribution is not adequate due to the leptokurtic nature of the data. Major features in the S&P 500 index, such as regime identification, volatility clustering, and anti-correlation between return and volatility, can be extracted from HMM cleanly. Univariate symmetric lambda distribution is essentially a location-scale family of power-exponential distribution. Such distribution is suitable for describing highly leptokurtic time series obtained from the financial market.

## Details

The main change compared to a normal-distribution based HMM is to add the third parameter `lambda` to describe the kurtosis level of the distribution. When `lambda` is one, the model converges back to a normal-distribution based HMM (e.g. using `depmixS4` package). The ability to optimize kurtosis brings the model output to be more consistent with the data. In particular, for daily data, the level of kurtosis is quite high. This puts the normal distribution in great disadvantage. This problem is solved by using the lambda distribution.

ldhmm *Constructor of ldhmm class*

---

### Description

Construct an ldhmm class by providing the required parameters.

### Usage

```
ldhmm(m, param, gamma, delta = NULL, stationary = TRUE,  
      mle.optimizer = "nlm")
```

### Arguments

m	numeric, number of states
param	matrix, the ecd parameters of states.
gamma	numeric or matrix, the transition probability matrix, must be conformed to m by m. if provided as vector, it will be converted to a matrix with byrow=TRUE.
delta	numeric, the initial distribution for each state, default is NULL.
stationary	logical, specify whether the initial distribution is stationary or not, default is TRUE.
mle.optimizer	character, specify alternative optimizer, default is nlm.

### Value

An object of ldhmm class

### Author(s)

Stephen H. Lihn

### Examples

```
param0 <- matrix(c(0.003, 0.02, 1, -0.006, 0.03, 1.3), 2, 3, byrow=TRUE)  
gamma0 <- matrix(c(0.9, 0.1, 0.1, 0.9), 2, 2, byrow=TRUE)  
d <- ldhmm(m=2, param=param0, gamma=gamma0)
```

---

 ldhmm-class

*The ldhmm class*

---

## Description

This S4 class is the major object class for ldhmm package

## Slots

call The match.call slot

m numeric, length 1, number of states

param.nbr numeric, number of parameters (2 or 3) for each ecld object

param matrix, natural parameters for ecld objects, size of states times param.nbr. Each row can be 2-parameter sequences, or 3-parameter sequences. Three-parameter unit ( $\mu$ ,  $\sigma$ ,  $\lambda$ ) forms an ecld object representing a leptokurtic symmetric lambda distribution. On the other hand, to provide compatibility to a normal distribution HMM, two-parameter unit ( $\mu$ ,  $\sigma$ ) forms an ecld object with  $\lambda=1$ .

gamma matrix, the transition probability matrix, must be m by m.

delta numeric, the initial distribution for each state, default is NULL.

stationary logical, specify whether the initial distribution is stationary or not, default is TRUE.

mle.optimizer character, the MLE optimizer. Currently it is just set to "nlm".

return.code numeric, the return code from the MLE optimizer.

iterations numeric, number of iterations MLE optimizer takes.

mllk numeric, the final mllk value.

AIC numeric, the final AIC.

BIC numeric, the final BIC.

observations numeric, stores the observations post optimization

states.prob matrix, stores the state probabilities post optimization

states.local numeric, stores the local decoding states post optimization

states.global numeric, stores the global decoding states post optimization (Viterbi)

states.local.stats matrix, stores the statistics of local states post optimization

states.global.stats matrix, stores the statistics of global states post optimization

---

 ldhmm.calc\_stats\_from\_obs

*Computing the statistics for each state*

---

### Description

This utility computes the statistics (mean, sd, kurtosis, length) for each state. It can be based on the local or global decoding result. The concept of asymptotic statistics can be applied by which the largest N observations (in absolute term) can be dropped to avoid distortion from outliers. It is assumed the object already has come with filled data in observations, states.prob, states.local, states.global slots.

### Usage

```
ldhmm.calc_stats_from_obs(object, drop = 0, use.local = TRUE)
```

```
ldhmm.drop_outliers(x, drop = 1)
```

### Arguments

object	an ldhmm object that contains the observations.
drop	numeric, an integer to drop the largest N observations, default is zero.
use.local	logical, use local decoding result, default is TRUE. Otherwise, use global decoding result.
x	numeric, the observations.

### Value

an ldhmm object containing results of decoding

### Author(s)

Stephen H. Lihn

---

 ldhmm.conditional\_prob

*Computing the conditional probabilities*

---

### Description

This utility computes the conditional probabilities that observation at time t equals xc, given all observations other than that at time t being the same.

**Usage**

```
ldhmm.conditional_prob(object, x, xc)
```

**Arguments**

object	an ldhmm object
x	numeric, the observations.
xc	numeric, the conditional observations.

**Value**

matrix of probabilities, size of xc times size of x.

**Author(s)**

Stephen H. Lihn

---

ldhmm.decode\_stats\_history

*Estimating historical statistics (mean, volatility and kurtosis)*

---

**Description**

This utility estimates historical statistics (mean, volatility and kurtosis) according to the state probabilities. The ldhmm object must have been decoded by running through ldhmm.decoding function. Note that kurtosis is naively implemented as the linear sum from each state weighted by state probabilities. It is subject to change to more rigorous formula in future releases.

**Usage**

```
ldhmm.decode_stats_history(object, ma.order = 0, annualize = FALSE,
  days.pa = 252)
```

**Arguments**

object	a decoded ldhmm object
ma.order	a positive integer or zero, specifying order of moving average. Default is zero.
annualize	logical, to annualize the sd and mean to $V(x\sqrt{\text{days.pa}} \times 100)$ and $R(x\text{days.pa})$ . Default is FALSE.
days.pa	a positive integer, specifying number of days per year, default is 252.

**Value**

an matrix of statistics history, size of observations times size of 3

**Author(s)**

Stephen H. Lihn

---

ldhmm.decoding      *Computing the minus log-likelihood (MLLK)*

---

### Description

This utility computes the state probabilities, uses local and global decoding to calculate the states. The results are saved to the returned ldhmm object.

### Usage

```
ldhmm.decoding(object, x)
```

### Arguments

object	an ldhmm object
x	numeric, the observations.

### Value

an ldhmm object containing results of decoding

### Author(s)

Stephen H. Lihn

---

ldhmm.forecast\_prob      *Computing the forecast probability distribution*

---

### Description

This utility computes the forecast probability distribution (Zucchini, 5.3)

### Usage

```
ldhmm.forecast_prob(object, x, xf, h = 1)
```

### Arguments

object	an ldhmm object
x	numeric, the observations.
xf	numeric, the future observations to be forecasted.
h	integer, time steps to forecast.

### Value

matrix of probabilities, size of h times size of xf.

**Author(s)**

Stephen H. Lihn

---

ldhmm.forecast\_state *Computing the state forecast*

---

**Description**

This utility computes the state forecast, given the sequence of observations in the past.

**Usage**

```
ldhmm.forecast_state(object, x, h = 1)
```

**Arguments**

object	an ldhmm object
x	numeric, the observations.
h	integer, time steps to forecast.

**Value**

matrix of probabilities per state (even if h=1), number of states times size of h

**Author(s)**

Stephen H. Lihn

---

ldhmm.forecast\_volatility  
*Computing the volatility forecast for next one period*

---

**Description**

This utility computes the volatility forecast based on the given future observations for next one period.

**Usage**

```
ldhmm.forecast_volatility(object, x, xf, ma.order = 0, days.pa = 252)
```

**Arguments**

object	an ldhmm object
x	numeric, the observations.
xf	numeric, the future observations to be forecasted.
ma.order	a positive integer or zero, specifying order of moving average. Default is zero.
days.pa	a positive integer specifying trading days per year, default is 252.

**Value**

matrix of future observations and volatilities, size of 2 times length of xf.

**Author(s)**

Stephen H. Lihn

---

ldhmm.fred_data	<i>Utility to download time series from FRED</i>
-----------------	--

---

**Description**

This utility downloads time series from FRED. It serves as a data source for daily data, e.g. SP500 for S&P 500, and VIXCLS for CBOE VIX index. This can be concatenated to the static data to provide daily updates.

**Usage**

```
ldhmm.fred_data(symbol, col_out = "Close", do.logr = TRUE)
```

**Arguments**

symbol	character, the name of the time series
col_out	character, the name of the output closing price column. Default: "Close"
do.logr	logical, if TRUE (default), produce xts object of logr; otherwise, just the col_out column. Be aware that, because logr uses diff, the first day close will be deleted.

**Value**

The xts object for the time series

**Examples**

```
## Not run:
ldhmm.fred_data("VIXCLS")

## End(Not run)
```

---

ldhmm.gamma_init	<i>Initializing transition probability paramter</i>
------------------	---

---

### Description

This utility has multiple purposes. It can generate a simple transition probability matrix, using p1 and p2, if prob is left as NULL. The generated gamma is raw and not normalized. If prob is provided as a vector, the utility converts it into a matrix as gamma. Furthermore, if prob is provided as a vector or matrix, the utility applies min.gamma, and normalize the sum of t.p.m. rows to 1. This is mainly an internal function used by MLE, not be concerned by external users.

### Usage

```
ldhmm.gamma_init(m, p1 = 0.04, p2 = 0.01, prob = NULL,  
  min.gamma = 0)
```

### Arguments

m	numeric, number of states
p1	numeric, the first-neighbor transition probability, default is 0.04.
p2	numeric, the second-neighbor transition probability, default is 0.01.
prob	numeric or matrix, a fully specified transition probability by user, default is NULL. If this is specified, p1, p2 would be ignored.
min.gamma	numeric, a minimum transition probability added to gamma to avoid singularity, default is 0. This is only used when prob is not NULL.

### Value

a matrix as gamma

### Author(s)

Stephen H. Lihn

### Examples

```
gamma0 <- ldhmm.gamma_init(m=3)  
prob=c(0.9, 0.1, 0.1,  
  0.1, 0.9, 0.0,  
  0.1, 0.1, 0.8)  
gamma1 <- ldhmm.gamma_init(m=3, prob=prob)  
gamma2 <- ldhmm.gamma_init(m=2, prob=gamma1, min.gamma=1e-6)
```

---

ldhmm.ld_stats	<i>Computes the theoretical statistics per state</i>
----------------	--

---

**Description**

This utility computes the statistics (mean, sd, kurtosis) based on the lambda distribution. This is used to compare to the statistics from observations for each state.

**Usage**

```
ldhmm.ld_stats(object, annualize = FALSE, days.pa = 252)
```

**Arguments**

object	an ldhmm object
annualize	logical, to annaulize the sd and mean to $V(x\sqrt{\text{days.pa}} \times 100)$ and $R(x\text{days.pa})$ . Default is FALSE.
days.pa	a positive integer, specifying number of days per year, default is 252.

**Value**

a matrix of statistics for each state, size of states times 3

**Author(s)**

Stephen H. Lihn

---

ldhmm.log_forward	<i>Computing the log forward and backward probabilities</i>
-------------------	---

---

**Description**

This utility computes the logarithms of the forward and backward probabilities, aka alpha and beta. The logarithm keeps the computation away from floating point under/over-flow. (Zucchini, 5.4)

**Usage**

```
ldhmm.log_forward(object, x)
```

```
ldhmm.log_backward(object, x)
```

**Arguments**

object	an ldhmm object
x	numeric, the observations.

**Value**

numeric, the log probabilities

**Author(s)**

Stephen H. Lihn

---

 ldhmm.mle

---

*Computing the MLEs*

---

**Description**

Computing the MLEs using nlm package

**Usage**

```
ldhmm.mle(object, x, min.gamma = 1e-06, decode = FALSE,
  plot.fn = NULL, plot.interval = 200, ssm.fn = NULL,
  print.level = 0, iterlim = 1000, ...)
```

**Arguments**

object	an ldhmm object that can supply m, param.nbr and stationary.
x	numeric, the observations.
min.gamma	numeric, a minimum transition probability added to gamma to avoid singularity, default is 1e-6.
decode	logical, run decoding after optimization, default is FALSE.
plot.fn	name of the function that takes ldhmm object. It will be called occasionally to track the progress of the fit, mainly by plotting the time series and states. E.g. When one fits the SPX index, the function ldhmm.oxford_man_plot_obs can be used to show the expected volatility vs Oxford-Man realized volatility. Default is NULL.
plot.interval	a positive integer, specifying how often to invoke plot function, default is 200 iterations.
ssm.fn	name of the function that takes ldhmm object. This function is called after the MLLK call. The purpose is to generate an additional score for optimization. E.g. It can be used to separate the states into predefined intervals, modeling a state space model. Default is NULL.
print.level	numeric, this argument determines the level of printing which is done during the minimization process. The default value of 0 means that no printing occurs, a value of 1 means that initial and final details are printed and a value of 2 means that full tracing information is printed.
iterlim	numeric, a positive integer specifying the maximum number of iterations to be performed before the program is terminated.
...	additional parameters passed to the MLE optimizer

**Value**

an ldhmm object containing results of MLE optimization

**Author(s)**

Stephen H. Lihn

**Examples**

```
## Not run:
  param0 <- matrix(c(0.003, 0.02, 1, -0.006, 0.03, 1.3), 2, 3, byrow=TRUE)
  gamma0 <- ldhmm.gamma_init(m=2, prob=c(0.9, 0.1, 0.1, 0.9))
  h <- ldhmm(m=2, param=param0, gamma=gamma0)
  spx <- ldhmm.ts_log_rtn()
  ldhmm.mle(h, spx$x)

## End(Not run)
```

---

 ldhmm.mllk

---

*Computing the minus log-likelihood (MLLK)*

---

**Description**

This utility computes the MLLK. It is typically invoked by the MLE optimizer. (Zucchini, 3.2)

**Usage**

```
ldhmm.mllk(object, x, mllk.print.level = 0)
```

**Arguments**

object	an input ldhmm object to provide static reference, such as m, param.nbr, stationary.
x	numeric, the observations.
mllk.print.level	numeric, this argument determines the level of printing which is done during the minimization process. The default value of 0 means that no printing occurs, a value of 1 or greater means some tracing information is printed.

**Value**

an ldhmm object containing results of MLE optimization

**Author(s)**

Stephen H. Lihn

---

 ldhmm.n2w

*Transforming natural parameters to a linear working parameter array*

---

**Description**

This utility linearizes the natural parameters and transforms the constrained parameters to unconstrained parameters. (Zucchini, 3.3.1)

**Usage**

```
ldhmm.n2w(object, mu.scale = 1)
```

**Arguments**

object	an ldhmm object
mu.scale	numeric, if provided, e.g. <code>mean(abs(x))</code> , it is used to scale up mu so that the scale is more friendly to the optimizer. Default is 1.

**Value**

numeric, linear working parameter array

**Author(s)**

Stephen H. Lihn

**Examples**

```
param0 <- matrix(c(0.003, 0.02, 1, -0.006, 0.03, 1.3), 2, 3, byrow=TRUE)
gamma0 <- matrix(c(0.9, 0.1, 0.1, 0.9), 2, 2, byrow=TRUE)
d <- ldhmm(m=2, param=param0, gamma=gamma0)
v <- ldhmm.n2w(d)
```

---

 ldhmm.oxford\_man\_index\_list

*Get the index list from Oxford-Man*

---

**Description**

This utility shows the index list within the Oxford-Man data set.

**Usage**

```
ldhmm.oxford_man_index_list()
```

**Value**

character, list of indices

**Author(s)**

Stephen H. Lihn

**References**

Oxford-Man Institute of Quantitative Finance. Realized Library: <http://realized.oxford-man.ox.ac.uk>

**Examples**

```
## Not run:
  ldhmm.oxford_man_index_list()

## End(Not run)
```

---

ldhmm.oxford\_man\_plot\_obs

*Plotting Oxford-Man realized volatility overlaid with HMM expected volatility*

---

**Description**

This utility plots the Oxford-Man realized volatility (from SPX2.rv) and overlays with the HMM expected volatility with the observations set up SPX2.r. This graph is to show that the HMM is capable of reproducing the realized volatility. Optionally the insert shows the relation between the return and volatility indicated by each state. This plot is also called "volatility yield curve".

**Usage**

```
ldhmm.oxford_man_plot_obs(object, days.pa = 252, start.date = NULL,
  end.date = NULL, index.symbol = ".SPX", index.rv = "rv5",
  index.px = "close_price", index.px.scale = 15,
  index.px.origin = NULL, index.vol.ma.order = 5,
  vix.adj.ratio = NULL, insert.plot = TRUE, insert.viewport = NULL)
```

**Arguments**

object	an ldhmm object with a stationary solution. If this is set to NULL, an internal 10-state HMM object will be used.
days.pa	a positive integer specifying trading days per year, default is 252.
start.date	Date or character of ISO format (YYYY-MM-DD), specifying the start date of the plot, default is NULL.
end.date	Date or character of ISO format (YYYY-MM-DD), specifying the end date of the plot, default is NULL.

<code>index.symbol</code>	character, the symbol of the index. Default is <code>.SPX</code> .
<code>index.rv</code>	character, specifying index realized variance column, default is <code>rv5</code> .
<code>index.px</code>	character, specifying index closing price column, default is <code>close_price</code> .
<code>index.px.scale</code>	numeric, specifying the scaling factor when plotting price trend, default is 15. Set this to NULL if you don't wish to see the price line. The closing price is converted to cumulative return by the price of the first date. Then plot from the mid-point of volatility axis with this scale.
<code>index.px.origin</code>	numeric, specifying the starting value of the index price line, the default is NULL, which will start the index price line from the middle of y-axis.
<code>index.vol.ma.order</code>	a positive integer specifying the simple moving average of the realized volatility, default is 5. This is needed because the realized volatility is very noisy at the daily level.
<code>vix.adj.ratio</code>	numeric, if specified, VIX index is adjusted and plotted, default is NULL. The long-term ratio between VIX and 10-state HMM is 0.79. The VIX data is cached when the Oxford data is downloaded.
<code>insert.plot</code>	logical, if true, also plot the volatility-return as insert in upper-right corner, default is TRUE.
<code>insert.viewport</code>	optional viewport for the insert, default is NULL, which is internally set to <code>grid::viewport(.8, .75, .3, .3)</code> .

**Author(s)**

Stephen H. Lihn

**Examples**

```
## Not run:
  ldhmm.oxford_man_plot_obs(NULL)

## End(Not run)
```

---

 ldhmm.oxford\_man\_realized\_data

*Get the realized data from Oxford-Man*

---

**Description**

This utility fetches the realized data from Oxford-Man and stores the data frame in local memory. It can be retrieved as `getOption("ldhmm.oxford.rv")`. Since the data is updated on a daily basis. The user can optionally force the utility to fetch the new file in the same R-session. Note that the download is network intensive. The size of file is about 10-20 MB and growing daily. In addition, VIX daily data is downloaded as `getOption("ldhmm.oxford.vix")`.

**Usage**

```
ldhmm.oxford_man_realized_data(force = FALSE, debug = FALSE)
```

**Arguments**

force                    logical, force the utility to fetch the new file. Default is FALSE.  
 debug                   logical, print debug information. Could be very verbose. Default is FALSE.

**Value**

data.frame containing the raw data from Oxford-Man.

**Author(s)**

Stephen H. Lihn

**References**

Oxford-Man Institute of Quantitative Finance. Realized Library: <http://realized.oxford-man.ox.ac.uk>

**Examples**

```
## Not run:
  ldhmm.oxford_man_realized_data()

## End(Not run)
```

---

ldhmm.oxford\_man\_ts    *Get time series from Oxford-Man Realized data set*

---

**Description**

This utility returns the time series from the specific column in Oxford-Man Realized data set.

**Usage**

```
ldhmm.oxford_man_ts(symbol, column, log = FALSE, to.vol = FALSE,
  days.pa = 252)
```

**Arguments**

symbol                   character, specify the index name, e.g. ".SPX".  
 column                   character, the column name, e.g. "rv5".  
 log                      logical, take one plus log to convert return to log-return. Default is FALSE.  
 to.vol                   logical, take  $\sqrt{x \times 252} \times 100$  to convert variance to annualized volatility. Default is FALSE.  
 days.pa                 a positive integer specifying number of days to annualize volatility. Default is 252.

**Value**

an xts object containing the time series, with dates as index

**Author(s)**

Stephen H. Lihn

**Examples**

```
## Not run:
  vol <- ldhmm.oxford_man_ts(".SPX", "rv5", to.vol=TRUE)

---

ldhmm.plot\_spx\_vix\_obs

*Plotting HMM expected volatility for SPX overlaid with adjusted VIX*

---

**Description**

This utility plots the HMM expected volatility of SPX overlaid with the VIX index adjusted by a ratio. The expected volatility is shown to have a long-term ratio of 0.79 relative to the VIX index. This plot will show how HMM deviates from VIX in a shorter time window. Optionally the insert shows the relation between the return and volatility indicated by each state. This plot is also called "volatility yield curve".

**Usage**

```
ldhmm.plot_spx_vix_obs(object, days.pa = 252, start.date = NULL,
  end.date = NULL, px.origin = NULL, px.scale = NULL,
  vix.adj.ratio = NULL, insert.plot = TRUE, insert.viewport = NULL)
```

**Arguments**

object	an ldhmm object with a stationary solution. If this is set to NULL, an internal 10-state HMM object will be used.
days.pa	a positive integer specifying trading days per year, default is 252.
start.date	Date or character of ISO format (YYYY-MM-DD), specifying the start date of the plot, default is NULL, which is converted to 1.5 years ago.
end.date	Date or character of ISO format (YYYY-MM-DD), specifying the end date of the plot, default is NULL, which means the latest date.
px.origin	numeric, specifying the starting value of the index price line, the default is NULL, which will start the index price line from the middle of y-axis.
px.scale	numeric, specifying the scaling factor when plotting price trend, default is 15. The closing price is converted to cumulative return by the price of the first date. Then plot from the mid-point of volatility axis with this scale.

`vix.adj.ratio` numeric, if specified, VIX index is adjusted and plotted, default is NULL. Default is to use the long-term ratio between VIX and 10-state HMM, which is about 0.79.

`insert.plot` logical, if true, also plot the volatility-return as insert in upper-right corner, default is TRUE.

`insert.viewport` optional viewport for the insert, default is NULL, which is internally set to `grid::viewport(.8, .75, .3, .3)`.

Stephen H. Lihn

**Examples**

```
## Not run:
  ldhmm.plot_spx_vix_obs(h)

## End(Not run)
```

---

`ldhmm.pseudo_residuals`

*Computing pseudo-residuals*

---

**Description**

This utility computes pseudo-residuals. (Zucchini, 6.2)

**Usage**

```
ldhmm.pseudo_residuals(object, x, xc.length = 1000)
```

**Arguments**

`object` an `ldhmm` object

`x` numeric, the observations.

`xc.length` a positive integer specifying the length of `xc` when calculating conditional probabilities, default is 1000.

**Value**

a vector of normal quantiles

**Author(s)**

Stephen H. Lihn

**Examples**

```
## Not run:
sr <- ldhmm.pseudo_residuals(object, x)
hist(sr)
acf(sr)
qqnorm(sr, cex=0.5)
L <- seq(-3,3,length.out=100)
lines(L,L,col="red",lwd=2, lty=2)

## End(Not run)
```

---

```
ldhmm.read_sample_object
      Read sample ldhmm object
```

---

**Description**

This utility is used to read sample ldhmm object so that the user doesn't need to go through lengthy optimization process to obtain a trained HMM for advanced features.

**Usage**

```
ldhmm.read_sample_object(symbol = "spx-daily-m10", extdata_dir = NULL)
```

**Arguments**

symbol	Character for the symbol of the time series. Default is spx-daily-m10
extdata_dir	optionally specify user's own extdata folder

**Value**

The ldhmm object

**Author(s)**

Stephen H-T. Lihn

**Examples**

```
hs <- ldhmm.read_sample_object() # SPX daily 10-state HMM
```

`ldhmm.simulate_abs_acf`*Simulating auto-correlation (ACF)*

---

**Description**

This utility simulates the auto-correlation. The first few lag of ACF should match the ACF from the market data fairly well. This is a major validation of a successful HMM. Be aware this is a CPU intensive calculation. It uses the multi-core functionality.

**Usage**

```
ldhmm.simulate_abs_acf(object, n = 10000, lag.max = 5, debug = FALSE)
```

**Arguments**

<code>object</code>	an ldhmm object that can supply <code>m</code> , <code>param.nbr</code> and <code>stationary</code> .
<code>n</code>	a positive integer specifying number of observations to simulate.
<code>lag.max</code>	a positive integer, specifying number of lags to be computed.
<code>debug</code>	logical, specifying to print progress message or not. Default is FALSE.

**Value**

a vector of ACF

**Author(s)**

Stephen H. Lihn

---

`ldhmm.simulate_state_transition`*Simulating state transition*

---

**Description**

This utility allows to simulate the states and observations over time. Be aware this is a CPU intensive calculation. It uses the multi-core functionality.

**Usage**

```
ldhmm.simulate_state_transition(object, init = NULL)
```

**Arguments**

`object` an ldhmm object that can supply `m`, `param.nbr` and `stationary`.

`init` a positive integer specifying number of observations to simulate initially. The default is `NULL`, indicating that the simulation should use the (local) states and observations from within the object, and simulate the next set of random states and observations according to `gamma`. When `init` is an integer, the utility will generate random states and observations according to `delta`.

**Value**

an ldhmm object containing the simulated states and observations. The observations are stored in the `observations` slot. The states are stored in the `states.local` slot.

**Author(s)**

Stephen H. Lihn

---

ldhmm.sma	<i>Simple moving average of a time series</i>
-----------	---

---

**Description**

This utility calculates simple moving average, with option to backfill for NA.

**Usage**

```
ldhmm.sma(x, order, na.backfill = TRUE)
```

**Arguments**

`x` numeric, the time series.

`order` a positive integer to specify order of moving average.

`na.backfill` logical, specify whether to backfill for NA. Default is `TRUE`.

**Value**

numeric, simple moving average, same length as `x`.

**Author(s)**

Stephen H. Lihn

**Examples**

```
x <- 1:100
a <- ldhmm.sma(x, 10)
```

---

ldhmm.state\_ld                    *Constructing the ecd objects per state*

---

**Description**

This utility constructs the ecd objects per state and return them in a list of easy query.

**Usage**

```
ldhmm.state_ld(object, state = NULL)
```

**Arguments**

object	an ldhmm object
state	numeric, the states.

**Value**

a list of ecd objects

**Author(s)**

Stephen H. Lihn

---

ldhmm.state\_pdf                    *Computing the PDF per state given the observations*

---

**Description**

Computing the PDF per state given the observations. Only one of state or x can be a vector per call.

**Usage**

```
ldhmm.state_pdf(object, state, x)
```

**Arguments**

object	an ldhmm object
state	numeric, the states.
x	numeric, the observations.

**Value**

a vector or matrix of PDF. The dimension of matrix is state times x

**Author(s)**

Stephen H. Lihn

---

ldhmm.ts\_abs\_acf      *Computing ACF of the absolute value of a time series*

---

### Description

This utility computes the ACF of the absolute value of a time series as a proxy of the auto-correlation of the volatility. It allows to drop the largest N outliers so that they would not skew the ACF calculation.

### Usage

```
ldhmm.ts_abs_acf(x, drop = 0, lag.max = 100)
```

### Arguments

x                    numeric, the observations.  
drop                a positive integer, specifying number of outliers to be dropped.  
lag.max             a positive integer, specifying number of lags to be computed.

### Value

a vector of ACF

### Author(s)

Stephen H. Lihn

---

ldhmm.ts\_log\_rtn      *Get log-returns from historic prices of an index*

---

### Description

This utility returns the dates and log-returns of an index available in ecd package. Note that the data from ecd package is static. A limited set of live daily time series can be appended from FRED, e.g. SPX, VIX, DJIA.

### Usage

```
ldhmm.ts_log_rtn(symbol = "spx", start.date = "1950-01-01",  
                  end.date = "2015-12-31", on = "weeks", fred.data = FALSE)
```

**Arguments**

symbol	character, specify the symbol of the index, default is spx.
start.date, end.date	Date or character of ISO format (YYYY-MM-DD), to specify the date range, default is from 1950-01-01 to 2015-12-31. Set start.date and end.date to NULL or "" if you wish to get the entire time series.
on	character, specify the interval, days, weeks, months. Default is weeks.
fred.data	logical, specify whether to append daily time series data from FRED, default is FALSE.

**Value**

list of three vectors: d is the dates and x is log-returns and p is prices

**Author(s)**

Stephen H. Lihn

**Examples**

```
a <- ldhmm.ts_log_rtn()
```

---

ldhmm.viterbi	<i>Computing the global decoding by the Viterbi algorithm</i>
---------------	---

---

**Description**

This utility computes the global decoding by the Viterbi algorithm.

**Usage**

```
ldhmm.viterbi(object, x)
```

**Arguments**

object	an ldhmm object
x	numeric, the observations.

**Value**

a vector of states

**Author(s)**

Stephen H. Lihn

---

 ldhmm.w2n

*Transforming working parameter array to natural parameters*

---

**Description**

This utility transforms the working parameter array back to the vectors and matrix of the constrained parameters. (Zucchini, 3.3.1)

**Usage**

```
ldhmm.w2n(object, par.vector, mu.scale = 1)
```

**Arguments**

object	an ldhmm object that can supply m, param.nbr and stationary.
par.vector	numeric, linear working parameter array. See ldhmm.n2w.
mu.scale	numeric, it should mirror what is provided to ldhmm.n2w. Default is 1.

**Value**

an ldhmm object

**Author(s)**

Stephen H. Lihn

---

 numericOrNull-class

*The numericOrNull class*

---

**Description**

The S4 class union of numeric and NULL, primarily used for delta
