Description

The package `opera` performs, for regression-oriented time-series, predictions by combining a finite set of forecasts provided by the user. More formally, it considers a sequence of observations \( Y \) (such as electricity consumption, or any bounded time series) to be predicted step by step. At each time instance \( t \), a finite set of experts (basically some based forecasters) provide predictions \( x \) of the next observation in \( y \). This package proposes several adaptive and robust methods to combine the expert forecasts based on their past performance.

}

print(head(MLpolBlock$weights))

---

**check_loss**

*Function to check validy of provided loss function*

**Description**

Function to check validy of provided loss function

**Usage**

```r
check_loss(
  loss.type,  # character,list or function.
  loss.gradient,
  Y = NULL,
  model = NULL,
  use_cpp = getOption("opera_use_cpp", default = FALSE)
)
```

**Arguments**

- **loss.type** character,list or function.
  - **character** Name of the loss to be applied ('square', 'absolute', 'percentage', or 'pinball');
  - **list** When using pinball loss: list with field name equal to 'pinball' and field tau equal to the required quantile in [0,1];
  - **function** A custom loss as a function of two parameters.
loss.gradient boolean, function.

**boolean** If TRUE, the aggregation rule will not be directly applied to the loss function at hand, but to a gradient version of it. The aggregation rule is then similar to gradient descent aggregation rule.

**function** If loss.type is a function, the derivative should be provided to be used (it is not automatically computed).

Y numeric (NULL). (Optional) Target values (to perform some checks).

model character (NULL). (Optional) Model used (to perform some checks).

use_cpp boolean. Whether or not to use cpp function to increase perf.

**Value**

loss.type

---

**check_matrix**

*Function to check and modify the input class and type*

**Description**

Function to check and modify the input class and type

**Usage**

`check_matrix(mat, name)`

**Arguments**

**mat** data.frame, data.table, tibble. Object to be cast to matrix.

**name** character. Name of the object to be cast.

**Value**

a 3d array if a 3d array is provided, else a matrix.
electric_load

Electricity forecasting data set

Description

Electricity forecasting data set provided by EDF R&D. It contains weekly measurements of the total electricity consumption in France from 1996 to 2009, together with several covariates, including temperature, industrial production indices (source: INSEE) and calendar information.

Usage

data(electric_load)

Format

An object of class data.frame with 731 rows and 11 columns.

Examples

data(electric_load)
  # a few graphs to display the data
  attach(electric_load)
  plot(Load, type = 'l')
  plot(Temp, Load, pch = 16, cex = 0.5)
  plot(NumWeek, Load, pch = 16, cex = 0.5)
  plot(Load, Load1, pch = 16, cex = 0.5)
  acf(Load, lag.max = 20)
  detach(electric_load)

FTRL

Implementation of FTRL (Follow The Regularized Leader)

Description

FTRL (Shalev-Shwartz and Singer 2007) and Chap. 5 of (Hazan 2019) is the online counterpart of empirical risk minimization. It is a family of aggregation rules (including OGD) that uses at any time the empirical risk minimizer so far with an additional regularization. The online optimization can be performed on any bounded convex set that can be expressed with equality or inequality constraints. Note that this method is still under development and a beta version.
Usage

FTRL(
  y,
  experts,
  eta = NULL,
  fun_reg = NULL,
  fun_reg_grad = NULL,
  constr_eq = NULL,
  constr_eq_jac = NULL,
  constr_ineq = NULL,
  constr_ineq_jac = NULL,
  loss.type = list(name = "square"),
  loss.gradient = TRUE,
  w0 = NULL,
  max_iter = 50,
  obj_tol = 0.01,
  training = NULL,
  default = FALSE,
  quiet = TRUE
)

Arguments

y vector. Real observations.
experts matrix. Matrix of experts previsions.
etat numeric. Regularization parameter.
fun_reg function (NULL). Regularization function to be applied during the optimization.
fun_reg_grad function (NULL). Gradient of the regularization function (to speed up the computations).
constr_eq function (NULL). Constraints (equalities) to be applied during the optimization.
constr_eq_jac function (NULL). Jacobian of the equality constraints (to speed up the computations).
constr_ineq function (NULL). Constraints (inequalities) to be applied during the optimization (... > 0).
constr_ineq_jac function (NULL). Jacobian of the inequality constraints (to speed up the computations).
loss.type character, list or function ("square").
  character Name of the loss to be applied ("square", "absolute", "percentage", or "pinball");
  list List with field name equal to the loss name. If using pinball loss, field tau equal to the required quantile in [0,1];
  function A custom loss as a function of two parameters (prediction, label).
**loss**

The function `loss` computes the sequence of instantaneous losses suffered by the predictions in `x` to predict the observation in `y`.

### Usage

```r
loss(
  x,
  y,
  pred = NULL,
  loss.type = list(name = "square"),
  loss.gradient = FALSE
)
```

### Arguments

- **loss.gradient**: boolean, function (TRUE).
  - boolean: If TRUE, the aggregation rule will not be directly applied to the loss function at hand, but to a gradient version of it. The aggregation rule is then similar to gradient descent aggregation rule.
  - function: If `loss.type` is a function, the derivative of the loss in its first component should be provided to be used (it is not automatically computed).
- **w0**: numeric (NULL). Vector of initialization for the weights.
- **max_iter**: integer (50). Maximum number of iterations of the optimization algorithm per round.
- **obj_tol**: numeric (1e-2). Tolerance over objective function between two iterations of the optimization.
- **training**: list (NULL). List of previous parameters.
- **default**: boolean (FALSE). Whether or not to use default parameters for `fun_reg`, `constr_eq`, `constr_ineq` and their `grad/jac`, which values are ALL ignored when TRUE.
- **quiet**: boolean (FALSE). Whether or not to display progress bars.

### Value

Object of class `mixture`.

### References

---

**loss**  
*Errors suffered by a sequence of predictions*

---

**Description**

The function `loss` computes the sequence of instantaneous losses suffered by the predictions in `x` to predict the observation in `y`.

**Usage**

```r
loss(
  x,
  y,
  pred = NULL,
  loss.type = list(name = "square"),
  loss.gradient = FALSE
)
```
Arguments

- **x** numeric. A vector of length \( T \) containing the sequence of prediction to be evaluated.
- **y** numeric. A vector of length \( T \) that contains the observations to be predicted.
- **pred** numeric. A vector of length \( T \) containing the sequence of real values.
- **loss.type** character, list or function ("square").
  - character Name of the loss to be applied ('square', 'absolute', 'percentage', or 'pinball');
  - list List with field name equal to the loss name. If using pinball loss, field \( \tau \) equal to the required quantile in \([0,1]\);
  - function A custom loss as a function of two parameters.
- **loss.gradient** boolean, function (TRUE).
  - boolean If TRUE, the aggregation rule will not be directly applied to the loss function at hand, but to a gradient version of it. The aggregation rule is then similar to gradient descent aggregation rule.
  - function If loss.type is a function, the derivative should be provided to be used (it is not automatically computed).

Value

A vector of length \( T \) containing the sequence of instantaneous losses suffered by the expert previ-
sions (x) or the gradient computed on the aggregated previsions (pred).

Author(s)

Pierre Gaillard <pierre@gaillard.me>

Description

The function `mixture` builds an aggregation rule chosen by the user. It can then be used to pre-
dict new observations \( Y \) sequentially. If observations \( Y \) and expert advice experts are provided,
mixture is trained by predicting the observations in \( Y \) sequentially with the help of the expert ad-
dvice in experts. At each time instance \( t = 1, 2, \ldots, T \), the mixture forms a prediction of \( Y[t,] \) by
assigning a weight to each expert and by combining the expert advice.

Usage

```r
mixture(
  Y = NULL,
  experts = NULL,
  model = "MLpol",
```
mixture

loss.type = "square",
loss.gradient = TRUE,
coefficients = "Uniform",
awake = NULL,
parameters = list(),
use_cpp = getOption("opera_use_cpp", default = FALSE),
quiet = TRUE
)

## S3 method for class 'mixture'
print(x, ...)

## S3 method for class 'mixture'
summary(object, ...)

Arguments

Y
A matrix with T rows and d columns. Each row Y[t,] contains a d-dimensional
observation to be predicted sequentially.

experts
An array of dimension c(T,d,K), where T is the length of the data-set, d the
dimension of the observations, and K is the number of experts. It contains the
expert forecasts. Each vector experts[t,,k] corresponds to the d-dimensional
prediction of Y[t,] proposed by expert k at time t = 1,...,T. In the case of
real prediction (i.e., d = 1), experts is a matrix with T rows and K columns.

model
A character string specifying the aggregation rule to use. Currently available
aggregation rules are:

'EWA' Exponentially weighted average aggregation rules (Cesa-Bianchi and
Lugosi 2006). A positive learning rate eta can be chosen by the user. The
bigger it is the faster the aggregation rule will learn from observations and
experts performances. However, too high values lead to unstable weight
vectors and thus unstable predictions. If it is not specified, the learning rate
is calibrated online. A finite grid of potential learning rates to be optimized
online can be specified with grid.eta.

'FS' Fixed-share aggregation rule (Cesa-Bianchi and Lugosi 2006). As for ewa,
a learning rate eta can be chosen by the user or calibrated online. The
main difference with ewa aggregation rule rely in the mixing rate alpha∈
[0, 1] which considers at each instance a small probability alpha to have a
rupture in the sequence and that the best expert may change. Fixed-share
aggregation rule can thus compete with the best sequence of experts that
can change a few times (see oracle), while ewa can only compete with the
best fixed expert. The mixing rate alpha is either chosen by the user
either calibrated online. Finite grids of learning rates and mixing rates to
be optimized can be specified with parameters grid.eta and grid.alpha.

'Ridge' Online Ridge regression (Cesa-Bianchi and Lugosi 2006). It mini-
mizes at each instance a penalized criterion. It forms at each instance linear
combination of the experts’ forecasts and can assign negative weights that
not necessarily sum to one. It is useful if the experts are biased or corre-
lated. It cannot be used with specialized experts. A positive regularization
Coefficient \texttt{lambda} can either be chosen by the user or calibrated online. A finite grid of coefficient to be optimized can be specified with a parameter \texttt{grid.lambda}.

'\texttt{MLpol}', '\texttt{MLewa}', '\texttt{MLprod}' Aggregation rules with multiple learning rates that are theoretically calibrated (Gaillard et al. 2014).

'\texttt{BOA}' Bernstein online Aggregation (Wintenberger 2017). The learning rates are automatically calibrated.

'\texttt{OGD}' Online Gradient descent (Zinkevich 2003). See also (Hazan 2019). The optimization is performed with a time-varying learning rate. At time step $t \geq 1$, the learning rate is chosen to be $t^{-\alpha}$, where $\alpha$ is provided by \texttt{alpha} in the parameters argument. The algorithm may or not perform a projection step into the simplex space (non-negative weights that sum to one) according to the value of the parameter 'simplex' provided by the user.

'\texttt{FTRL}' Follow The Regularized Leader (Shalev-Shwartz and Singer 2007). Note that here, the linearized version of FTRL is implemented (see Chap. 5 of (Hazan 2019)). FTRL is the online counterpart of empirical risk minimization. It is a family of aggregation rules (including OGD) that uses at any time the empirical risk minimizer so far with an additional regularization. The online optimization can be performed on any bounded convex set that can be expressed with equality or inequality constraints. Note that this method is still under development and a beta version.

The user must provide (in the \texttt{parameters}'s list):
- '\texttt{eta}' The learning rate.
- '\texttt{fun_reg}' The regularization function to be applied on the weights. See \texttt{auglag: fn}.
- '\texttt{constr_eq}' The equality constraints (e.g. $\text{sum}(w) = 1$). See \texttt{auglag: heq}.
- '\texttt{constr_ineq}' The inequality constraints (e.g. $w > 0$). See \texttt{auglag: hin}.
- '\texttt{fun_reg_grad}' (optional) The gradient of the regularization function. See \texttt{auglag: gr}.
- '\texttt{constr_eq_jac}' (optional) The Jacobian of the equality constraints. See \texttt{auglag: heq.jac}.
- '\texttt{constr_ineq_jac}' (optional) The Jacobian of the inequality constraints. See \texttt{auglag: hin.jac}.

or set \texttt{default} to TRUE. In the latter, FTRL is performed with Kullback regularization ($\text{fun_reg}(x) = \text{sum}(x \log (x/w0))$) on the simplex ($\text{constr_eq}(w) = \text{sum}(w) - 1$ and $\text{constr_ineq}(w) = w$). Parameters \texttt{w0} (weight initialization), and \texttt{max_iter} can also be provided.

\begin{description}
\item[\texttt{loss.type}] character, list, or function ("square").
\item[\texttt{character}] Name of the loss to be applied ('\texttt{square}', '\texttt{absolute}', '\texttt{percentage}', or '\texttt{pinball}');
\item[\texttt{list}] List with field name equal to the loss name. If using pinball loss, field \texttt{tau} equal to the required quantile in [0,1];
\item[\texttt{function}] A custom loss as a function of two parameters (prediction, observation). For example, $f(x,y) = \text{abs}(x-y)/y$ for the Mean absolute percentage error or $f(x,y) = (x-y)^2$ for the squared loss.
\end{description}
loss.gradient boolean, function (TRUE).

boolean If TRUE, the aggregation rule will not be directly applied to the loss function at hand, but to a gradient version of it. The aggregation rule is then similar to gradient descent aggregation rule.

function Can be provided if loss.type is a function. It should then be a sub-derivative of the loss in its first component (i.e., in the prediction). For instance, \( \delta g(x) = (x-y)\delta \) for the squared loss.

coefficients A probability vector of length K containing the prior weights of the experts (not possible for 'MLpol'). The weights must be non-negative and sum to 1.

awake A matrix specifying the activation coefficients of the experts. Its entries lie in \([0,1]\). Possible if some experts are specialists and do not always form and suggest prediction. If the expert number \( k \) at instance \( t \) does not form any prediction of observation \( Y_t \), we can put \( \text{awake}[t,k]=0 \) so that the mixture does not consider expert \( k \) in the mixture to predict \( Y_t \).

parameters A list that contains optional parameters for the aggregation rule. If no parameters are provided, the aggregation rule is fully calibrated online. Possible parameters are:

etta A positive number defining the learning rate. Possible if model is either 'EWA' or 'FS'

grid.eta A vector of positive numbers defining potential learning rates for 'EWA' of 'FS'. The learning rate is then calibrated by sequentially optimizing the parameter in the grid. The grid may be extended online if needed by the aggregation rule.

gamma A positive number defining the exponential step of extension of grid.eta when it is needed. The default value is 2.

alpha A number in \([0,1]\). If the model is 'FS', it defines the mixing rate. If the model is 'OGD', it defines the order of the learning rate: \( \eta_t = t^{-\alpha} \).

grid.alpha A vector of numbers in \([0,1]\) defining potential mixing rates for 'FS' to be optimized online. The grid is fixed over time. The default value is \([0.0001,0.001,0.01,0.1]\).

lambda A positive number defining the smoothing parameter of 'Ridge' aggregation rule.

grid.lambda Similar to grid.eta for the parameter lambda.

simplex A boolean that specifies if 'OGD' does a project on the simplex. In other words, if TRUE (default) the online gradient descent will be under the constraint that the weights sum to 1 and are non-negative. If FALSE, 'OGD' performs an online gradient descent on K dimensional real space without any projection step.

averaged A boolean (default is FALSE). If TRUE the coefficients and the weights returned (and used to form the predictions) are averaged over the past. It leads to more stability on the time evolution of the weights but needs more regularity assumption on the underlying process generating the data (i.i.d. for instance).

use_cpp boolean. Whether or not to use cpp optimization to fasten the computations. This option is not yet compatible with the use of custom loss function. Note that
cpp implementation corresponds to an earlier version of the code and may be outdated. Use options(opera_use_cpp = TRUE) to change the default value.

quiet  boolean. Whether or not to display progress bars.

x  An object of class mixture

...  Additional parameters

object  An object of class mixture

Value

An object of class mixture that can be used to perform new predictions. It contains the parameters model, loss.type, loss.gradient, experts, Y, awake, and the fields

coefficients  A vector of coefficients assigned to each expert to perform the next prediction.

weights  A matrix of dimension c(T,K), with T the number of instances to be predicted and K the number of experts. Each row contains the convex combination to form the predictions.

prediction  A matrix with T rows and d columns that contains the predictions outputted by the aggregation rule.

loss  The average loss (as stated by parameter loss.type) suffered by the aggregation rule.

parameters  The learning parameters chosen by the aggregation rule or by the user.

training  A list that contains useful temporary information of the aggregation rule to be updated and to perform predictions.

### oracle

**Compute oracle predictions**

**Description**

The function oracle performs a strategy that cannot be defined online (in contrast to mixture). It requires in advance the knowledge of the whole data set Y and the expert advice to be well defined. Examples of oracles are the best fixed expert, the best fixed convex combination rule, the best linear combination rule, or the best expert that can shift a few times.

**Usage**

oracle(
    Y,
    experts,
    model = "convex",
    loss.type = "square",
    awake = NULL,
    lambda = NULL,
    niter = NULL,
    ...
)
Arguments

Y  A vector containing the observations to be predicted.

experts  A matrix containing the experts forecasts. Each column corresponds to the predictions proposed by an expert to predict Y. It has as many columns as there are experts.

model  A character string specifying the oracle to use or a list with a component name specifying the oracle and any additional parameter needed. Currently available oracles are:

'expert'  The best fixed (constant over time) expert oracle.

'convex'  The best fixed convex combination (vector of non-negative weights that sum to 1)

'linear'  The best fixed linear combination of expert

'shifting'  It computes for all number $m$ of switches the sequence of experts with at most $m$ shifts that would have performed the best to predict the sequence of observations in Y.

loss.type  character, list or function.

character  Name of the loss to be applied ('square', 'absolute', 'percentage', or 'pinball');

list  When using pinball loss: list with field name equal to 'pinball' and field tau equal to the required quantile in [0,1];

function  A custom loss as a function of two parameters.

awake  A matrix specifying the activation coefficients of the experts. Its entries lie in $[0,1]$. Possible if some experts are specialists and do not always form and suggest prediction. If the expert number $k$ at instance $t$ does not form any prediction of observation $Y_t$, we can put $awake[t,k]=0$ so that the mixture does not consider expert $k$ in the mixture to predict $Y_t$. Remark that to compute the best expert oracle, the performance of unactive (or partially active) experts is computed by using the prediction of the uniform average of active experts.

lambda  A positive number used by the 'linear' oracle only. A possible $\lambda_2$ regularization parameter for computing the linear oracle (if the design matrix is not identifiable)

niter  A positive integer for 'convex' and 'linear' oracles if direct computation of the oracle is not implemented. It defines the number of optimization steps to perform in order to approximate the oracle (default value is 3).

Additional parameters that are passed to optim function in order to perform convex optimization (see parameter niter).

Value

An object of class 'oracle' that contains:

loss  The average loss suffered by the oracle. For the 'shifting' oracle, it is a vector of length $T$ where $T$ is the number of instance to be predicted (i.e., the length of the sequence Y). The value of $loss(m)$ is the loss (determined by the parameter loss.type) suffered by the best sequence of expert with at most $m-1$ shifts.
coefficients Not for the 'shifting' oracle. A vector containing the best weight vector corresponding to the oracle.

prediction Not for the 'shifting' oracle. A vector containing the predictions of the oracle.

rmse If loss.type is the square loss (default) only. The root mean square error (i.e., it is the square root of loss.

---

**plot.mixture**

*Plot an object of class mixture*

### Description

Provides different diagnostic plots for an aggregation procedure.

### Usage

```r
## S3 method for class 'mixture'
plot(
x,  
pause = FALSE,  
col = NULL,  
alpha = 0.01,  
dynamic = T,  
type = "all",  
max_experts = 50,  
col_by_weight = TRUE,  
...  
)
```

### Arguments

- **x**
  - an object of class mixture. If awake is provided (i.e., some experts are unactive), their residuals and cumulative losses are computed by using the predictions of the mixture.

- **pause**
  - if set to TRUE (default) displays the plots separately, otherwise on a single page

- **col**
  - the color to use to represent each experts, if set to NULL (default) use RColorBrewer::brewer.pal(...)

- **alpha**
  - numeric. Smoothing parameter for contribution plot (parameter ‘f’ of function lowess).

- **dynamic**
  - boolean. If TRUE, graphs are generated with rAmCharts, else with base R.

- **type**
  - char.
    - 'all' Display all the graphs ;
• 'plot_weight', 'boxplot_weight', 'dyn_avg_loss', 'cumul_res', 'avg_loss', 'contrib' Display the selected graph alone.

max_experts integer. Maximum number of experts to be displayed (only the more influential).

col_by_weight boolean. If TRUE (default), colors are ordered by weights of each expert, else by column

... additional plotting parameters

Value

plots representing: plot of weights of each expert in function of time, boxplots of these weights, cumulative loss $L_T = \sum_{t=1}^{T} l_{i,t}$ of each expert in function of time, cumulative residuals $\sum_{t=1}^{T} (y_t - f_{i,t})$ of each expert’s forecast in function of time, average loss suffered by the experts and the contribution of each expert to the aggregation $p_{i,t} f_{i,t}$ in function of time.

Functions to render dynamic mixture graphs using rAmCharts

Description

Functions to render dynamic mixture graphs using rAmCharts

Usage

plot_ridge_weights(data, colors = NULL, max_experts = 50, round = 3)
plot_weights(data, colors = NULL, max_experts = 50, round = 3)
boxplot_weights(data, colors = NULL, max_experts = 50)
plot_dyn_avg_loss(data, colors = NULL, max_experts = 50, round = 3)
plot_cumul_res(data, colors = NULL, max_experts = 50, round = 3)
plot_avg_loss(data, colors = NULL, max_experts = 50, round = 3)
plot_contrib(data, colors = NULL, alpha = 0.1, max_experts = 50, round = 3)

Arguments

data mixture object. Displays graphs.

colors character. Colors of the lines and bullets.

max_experts integer. Maximum number of experts to be displayed (only the more influential).

round integer. Precision of the displayed values.

alpha numeric. Smoothing parameter for contribution plot (parameter 'f' of function lowess).

Value

a rAmCharts plot
**plt_oracle_convex**  
*Functions to render dynamic oracle graphs using rAmCharts*

**Description**

Functions to render dynamic oracle graphs using rAmCharts

**Usage**

```r
plt_oracle_convex(data, colors, round = 2)
```

**Arguments**

- `data` named vector. Vector of values to be displayed.
- `colors` character. Colors to be used.
- `round` integer (2). Precision of the values in the tooltips.

**Value**

a rAmCharts plot

---

**predict.mixture**  
*Predict method for Mixture models*

**Description**

Performs sequential predictions and updates of a mixture object based on new observations and expert advice.

**Usage**

```r
## S3 method for class 'mixture'
predict(
  object,
  newexperts = NULL,
  newY = NULL,
  awake = NULL,
  online = TRUE,
  type = c("model", "response", "weights", "all"),
  use_cpp = getOption("opera_use_cpp", default = FALSE),
  quiet = TRUE,
  ...
)
```
Arguments

object Object of class inheriting from 'mixture'
newexperts An optional matrix in which to look for expert advice with which predict. If omitted, the past predictions of the object are returned and the object is not updated.
newY An optional matrix with d columns (or vector if d = 1) of observations to be predicted. If provided, it should have the same number of rows as the number of rows of newexperts. If omitted, the object (i.e, the aggregation rule) is not updated.
awake An optional array specifying the activation coefficients of the experts. It must have the same dimension as experts. Its entries lie in [0, 1]. Possible if some experts are specialists and do not always form and suggest prediction. If the expert number k at instance t does not form any prediction of observation Y_t, we can put awake[t, k]=0 so that the mixture does not consider expert k in the mixture to predict Y_t.
online A boolean determining if the observations in newY are predicted sequentially (by updating the object step by step) or not. If FALSE, the observations are predicting using the object (without using any past information in newY). If TRUE, newY and newexperts should not be null.
type Type of prediction. It can be
model return the updated version of object (using newY and newexperts).
response return the forecasts. If type is 'model', forecasts can also be obtained from the last values of object$prediction.
weights return the weights assigned to the expert advice to produce the forecasts. If type is 'model', forecasts can also be obtained from the last rows of object$weights.
all return a list containing 'model', 'response', and 'weights'.
use_cpp boolean. Whether or not to use cpp optimization to fasten the computations. This option is not yet compatible with the use of custom loss function.
quiet boolean. Whether or not to display progress bars.
... further arguments are ignored.

Value

predict.mixture produces a matrix of predictions (type = 'response'), an updated object (type = 'model'), or a matrix of weights (type = 'weights').
Description

The functions seriesToBlock and blockToSeries convert 1-dimensional series into series of higher dimension. For instance, suppose you have a time-series that consists of \( T = 100 \) days of \( d = 24 \) hours. The function seriesToBlock converts the time-series \( X \) of \( Td = 2400 \) observations into a matrix of size \( c(T=100,d=24) \), where each line corresponds to a specific day. This function is useful if you need to perform the prediction day by day, instead of hour by hour. The function can also be used to convert a matrix of expert prediction of dimension \( c(dT,K) \) where \( K \) is the number of experts, into an array of dimension \( c(T,d,K) \). The new arrays of observations and of expert predictions can be given to the aggregation rule procedure to perform \( d \)-dimensional predictions (i.e., day predictions).

Usage

```r
seriesToBlock(X, d)
blockToSeries(X)
```

Arguments

- **X**: An array or a vector to be converted.
- **d**: A positive integer defining the block size.

Details

The function blockToSeries performs the inverse operation.
