Package ‘parsnip’

July 20, 2021

Title A Common API to Modeling and Analysis Functions

Version 0.1.7

Maintainer Max Kuhn <max@rstudio.com>

Description A common interface is provided to allow users to specify a
model without having to remember the different argument names across
different functions or computational engines (e.g. 'R', 'Spark',
'Stan', etc).

add_rowindex

Add a column of row numbers to a data frame

Description
Add a column of row numbers to a data frame

Usage
add_rowindex(x)

Arguments
x A data frame

Value
The same data frame with a column of 1-based integers named .row.

Examples
mtcars %>% add_rowindex()

augment.model_fit Augment data with predictions

Description
augment() will add column(s) for predictions to the given data.

Usage
## S3 method for class 'model_fit'
augment(x, new_data, ...)

Arguments
x A model_fit object produced by fit.model_spec() or fit.xy.model_spec()
new_data A data frame or matrix.
... Not currently used.
Details

For regression models, a .pred column is added. If x was created using `fit.model_spec()` and new_data contains the outcome column, a .resid column is also added.

For classification models, the results can include a column called .pred_class as well as class probability columns named .pred.{level}. This depends on what type of prediction types are available for the model.

Examples

car_trn <- mtcars[11:32,]
car_tst <- mtcars[ 1:10,]

reg_form <-
  linear_reg() %>%
  set_engine("lm") %>%
  fit(mpg ~ ., data = car_trn)
reg_xy <-
  linear_reg() %>%
  set_engine("lm") %>%
  fit_xy(car_trn[, -1], car_trn$mpg)

augment(reg_form, car_tst)
augment(reg_form, car_tst[, -1])
augment(reg_xy, car_tst)
augment(reg_xy, car_tst[, -1])

# ------------------------------------------------------------------------------
data(two_class_dat, package = "modeldata")
cls_trn <- two_class_dat[-(1:10), ]
cls_tst <- two_class_dat[ 1:10 , ]

cls_form <-
  logistic_reg() %>%
  set_engine("glm") %>%
  fit(Class ~ ., data = cls_trn)
cls_xy <-
  logistic_reg() %>%
  set_engine("glm") %>%
  fit_xy(cls_trn[, -3],
         cls_trn$Class)

augment(cls_form, cls_tst)
augment(cls_form, cls_tst[, -3])
augment(cls_xy, cls_tst)
augment(cls_xy, cls_tst[, -3])
Description

boost_tree() defines a model that creates a series of decision trees forming an ensemble. Each tree depends on the results of previous trees. All trees in the ensemble are combined to produce a final prediction.

There are different ways to fit this model. See the engine-specific pages for more details:

- xgboost (default)
- C5.0
- spark

More information on how parsnip is used for modeling is at https://www.tidymodels.org/.

Usage

boost_tree(
  mode = "unknown",
  engine = "xgboost",
  mtry = NULL,
  trees = NULL,
  min_n = NULL,
  tree_depth = NULL,
  learn_rate = NULL,
  loss_reduction = NULL,
  sample_size = NULL,
  stop_iter = NULL
)

Arguments

mode A single character string for the prediction outcome mode. Possible values for this model are "unknown", "regression", or "classification".

engine A single character string specifying what computational engine to use for fitting.

mtry A number for the number (or proportion) of predictors that will be randomly sampled at each split when creating the tree models (specific engines only)

trees An integer for the number of trees contained in the ensemble.

min_n An integer for the minimum number of data points in a node that is required for the node to be split further.

tree_depth An integer for the maximum depth of the tree (i.e. number of splits) (specific engines only).

learn_rate A number for the rate at which the boosting algorithm adapts from iteration-to-iteration (specific engines only).

loss_reduction A number for the reduction in the loss function required to split further (specific engines only).

sample_size A number for the number (or proportion) of data that is exposed to the fitting routine. For xgboost, the sampling is done at each iteration while C5.0 samples once during training.

stop_iter The number of iterations without improvement before stopping (specific engines only).
This function only defines what type of model is being fit. Once an engine is specified, the method to fit the model is also defined.

The model is not trained or fit until the `fit.model_spec()` function is used with the data.

Examples

```r
show_engines("boost_tree")
boost_tree(mode = "classification", trees = 20)
```
contr_one_hot

Value
An S3 object with class "fit_control" that is a named list with the results of the function call

contr_one_hot

Contrast function for one-hot encodings

Description
This contrast function produces a model matrix with indicator columns for each level of each factor.

Usage
contr_one_hot(n, contrasts = TRUE, sparse = FALSE)

Arguments
n
A vector of character factor levels or the number of unique levels.

contrasts
This argument is for backwards compatibility and only the default of TRUE is supported.

sparse
This argument is for backwards compatibility and only the default of FALSE is supported.

Details
By default, model.matrix() generates binary indicator variables for factor predictors. When the formula does not remove an intercept, an incomplete set of indicators are created; no indicator is made for the first level of the factor.

For example, species and island both have three levels but model.matrix() creates two indicator variables for each:

library(dplyr)
library(modeldata)
data(penguins)

levels(penguins$species)
## [1] "Adelie"    "Chinstrap" "Gentoo"

levels(penguins$island)
## [1] "Biscoe"    "Dream"   "Torgersen"

model.matrix(~ species + island, data = penguins) %>%
  colnames()
## [1] "(Intercept)"  "speciesChinstrap" "speciesGentoo"  "islandDream"
## [5] "islandTorgersen"
For a formula with no intercept, the first factor is expanded to indicators for all factor levels but all other factors are expanded to all but one (as above):

```r
model.matrix(~ 0 + species + island, data = penguins) %>%
  colnames()
```

```r
## [1] "speciesAdelie"   "speciesChinstrap" "speciesGentoo"    "islandDream"
## [5] "islandTorgersen"
```

For inference, this hybrid encoding can be problematic. To generate all indicators, use this contrast:

```r
# Switch out the contrast method
old_contr <- options("contrasts")$contrasts
new_contr <- old_contr
new_contr["unordered"] <- "contr_one_hot"
options(contrasts = new_contr)

model.matrix(~ species + island, data = penguins) %>%
  colnames()
```

```r
## [1] "(Intercept)"  "speciesAdelie"    "speciesChinstrap" "speciesGentoo"
## [5] "islandBiscoe" "islandDream"     "islandTorgersen"
```

options(contrasts = old_contr)

Removing the intercept here does not affect the factor encodings.

**Value**

A diagonal matrix that is n-by-n.

---

**decision_tree**

**Decision trees**

**Description**

decision_tree() defines a model as a set of if/then statements that creates a tree-based structure.

There are different ways to fit this model. See the engine-specific pages for more details:

- `rpart` (default)
- `C5.0`
- `spark`

More information on how `parsnip` is used for modeling is at [https://www.tidymodels.org/](https://www.tidymodels.org/).
decision_tree

Usage

decision_tree(
    mode = "unknown",
    engine = "rpart",
    cost_complexity = NULL,
    tree_depth = NULL,
    min_n = NULL
)

Arguments

mode A single character string for the prediction outcome mode. Possible values for this model are "unknown", "regression", or "classification".

engine A single character string specifying what computational engine to use for fitting.

cost_complexity A positive number for the cost/complexity parameter (a.k.a. $C_p$) used by CART models (specific engines only).

tree_depth An integer for maximum depth of the tree.

Details

This function only defines what type of model is being fit. Once an engine is specified, the method to fit the model is also defined.

The model is not trained or fit until the `fit.model_spec()` function is used with the data.

Examples

show_engines("decision_tree")

decision_tree(mode = "classification", tree_depth = 5)
Data Set Characteristics Available when Fitting Models

Description

When using the `fit()` functions there are some variables that will be available for use in arguments. For example, if the user would like to choose an argument value based on the current number of rows in a data set, the `.obs()` function can be used. See Details below.

Usage

- `.cols()`
- `.preds()`
- `.obs()`
- `.lvls()`
- `.facts()`
- `.x()`
- `.y()`
- `.dat()`

Details

Existing functions:

- `.obs()`: The current number of rows in the data set.
- `.preds()`: The number of columns in the data set that is associated with the predictors prior to dummy variable creation.
- `.cols()`: The number of predictor columns available after dummy variables are created (if any).
- `.facts()`: The number of factor predictors in the data set.
- `.lvls()`: If the outcome is a factor, this is a table with the counts for each level (and `NA` otherwise).
- `.x()`: The predictors returned in the format given. Either a data frame or a matrix.
- `.y()`: The known outcomes returned in the format given. Either a vector, matrix, or data frame.
- `.dat()`: A data frame containing all of the predictors and the outcomes. If `fit_xy()` was used, the outcomes are attached as the column, `.y`.

For example, if you use the model formula `circumference ~ .` with the built-in `Orange` data, the values would be
.preds() = 2  (the 2 remaining columns in `Orange`)
.cols() = 5  (1 numeric column + 4 from Tree dummy variables)
.obs() = 35
.lvls() = NA  (no factor outcome)
.facts() = 1  (the Tree predictor)
.y() = <vector>  (circumference as a vector)
.x() = <data.frame> (The other 2 columns as a data frame)
.dat() = <data.frame> (The full data set)

If the formula `Tree ~ .` were used:

.pred() = 2  (the 2 numeric columns in `Orange`)
.cols() = 2  (same)
.obs() = 35
.lvls() = c("1" = 7, "2" = 7, "3" = 7, "4" = 7, "5" = 7)
.facts() = 0
.y() = <vector>  (Tree as a vector)
.x() = <data.frame> (The other 2 columns as a data frame)
.dat() = <data.frame> (The full data set)

To use these in a model fit, pass them to a model specification. The evaluation is delayed until the time when the model is run via `fit()` (and the variables listed above are available). For example:

```r
library(modeldata)
data("lending_club")
rand_forest(mode = "classification", mtry = .cols() - 2)
```

When no descriptors are found, the computation of the descriptor values is not executed.

---

**Extract elements of a parsnip model object**

**Description**

These functions extract various elements from a parsnip object. If they do not exist yet, an error is thrown.

- `extract_spec_parsnip()` returns the parsnip model specification.
- `extract_fit_engine()` returns the engine specific fit embedded within a parsnip model fit. For example, when using `linear_reg()` with the "lm" engine, this returns the underlying `lm` object.

**Usage**

```r
## S3 method for class 'model_fit'
extract_spec_parsnip(x, ...)

## S3 method for class 'model_fit'
extract_fit_engine(x, ...)
```
Arguments

x
A parsnip_model_fit object.
...
Not currently used.

Details

Extracting the underlying engine fit can be helpful for describing the model (via print(), summary(), plot(), etc.) or for variable importance/explainers.

However, users should not invoke the predict() method on an extracted model. There may be preprocessing operations that parsnip has executed on the data prior to giving it to the model. Bypassing these can lead to errors or silently generating incorrect predictions.

Good:

parsnip_fit %>% predict(new_data)

Bad:

parsnip_fit %>% extract_fit_engine() %>% predict(new_data)

Value

The extracted value from the parsnip object, \( x \), as described in the description section.

Examples

```r
lm_spec <- linear_reg() %>% set_engine("lm")
lm_fit <- fit(lm_spec, mpg ~ ., data = mtcars)

lm_spec
extract_spec_parsnip(lm_fit)

extract_fit_engine(lm_fit)
lm(mpg ~ ., data = mtcars)
```

---

**fit.model_spec**

Fit a Model Specification to a Dataset

Description

fit() and fit_xy() take a model specification, translate the required code by substituting arguments, and execute the model fit routine.

Usage

```r
## S3 method for class 'model_spec'
fit(object, formula, data, control = control_parsnip(), ...)

## S3 method for class 'model_spec'
fit_xy(object, x, y, control = control_parsnip(), ...)
```
Arguments

- **object**: An object of class `model_spec` that has a chosen engine (via `set_engine()`).
- **formula**: An object of class `formula` (or one that can be coerced to that class): a symbolic description of the model to be fitted.
- **data**: Optional, depending on the interface (see Details below). A data frame containing all relevant variables (e.g. outcome(s), predictors, case weights, etc). Note: when needed, a named argument should be used.
- **control**: A named list with elements `verbosity` and `catch`. See `control_parsnip()`.
- **...**: Not currently used; values passed here will be ignored. Other options required to fit the model should be passed using `set_engine()`.
- **x**: A matrix, sparse matrix, or data frame of predictors. Only some models have support for sparse matrix input. See `parsnip::get_encoding()` for details. x should have column names.
- **y**: A vector, matrix or data frame of outcome data.

Details

`fit()` and `fit_xy()` substitute the current arguments in the model specification into the computational engine’s code, check them for validity, then fit the model using the data and the engine-specific code. Different model functions have different interfaces (e.g. formula or x/y) and these functions translate between the interface used when `fit()` or `fit_xy()` was invoked and the one required by the underlying model.

When possible, these functions attempt to avoid making copies of the data. For example, if the underlying model uses a formula and `fit()` is invoked, the original data are references when the model is fit. However, if the underlying model uses something else, such as x/y, the formula is evaluated and the data are converted to the required format. In this case, any calls in the resulting model objects reference the temporary objects used to fit the model.

If the model engine has not been set, the model’s default engine will be used (as discussed on each model page). If the `verbosity` option of `control_parsnip()` is greater than zero, a warning will be produced.

Value

A `model_fit` object that contains several elements:

- `lvl`: If the outcome is a factor, this contains the factor levels at the time of model fitting.
- `spec`: The model specification object (`object` in the call to `fit`)
- `fit`: when the model is executed without error, this is the model object. Otherwise, it is a try-error object with the error message.
- `preproc`: any objects needed to convert between a formula and non-formula interface (such as the `terms` object)

The return value will also have a class related to the fitted model (e.g. "glm") before the base class of "model_fit".

See Also

Examples

# Although `glm()` only has a formula interface, different
# methods for specifying the model can be used

library(dplyr)
library(modeldata)
data("lending_club")

lr_mod <- logistic_reg()

using_formula <-
  lr_mod %>%
  set_engine("glm") %>%
  fit(Class ~ funded_amnt + int_rate, data = lending_club)

using_xy <-
  lr_mod %>%
  set_engine("glm") %>%
  fit_xy(x = lending_club[, c("funded_amnt", "int_rate")],
         y = lending_club$Class)

using_formula
using_xy

---

gen_additive_mod

Generalized additive models (GAMs)

Description

gen_additive_mod() defines a model that can use smoothed functions of numeric predictors
in a generalized linear model.

There are different ways to fit this model. See the engine-specific pages for more details

- mgcv (default)

More information on how parsnip is used for modeling is at https://www.tidymodels.org/.

Usage

gen_additive_mod(
  mode = "unknown",
  select_features = NULL,
  adjust_deg_free = NULL,
  engine = "mgcv"
)

Arguments

mode A single character string for the prediction outcome mode. Possible values
      for this model are "unknown", "regression", or "classification".
select_features  TRUE or FALSE. If TRUE, the model has the ability to eliminate a predictor (via penalization). Increasing adjust_deg_free will increase the likelihood of removing predictors.

adjust_deg_free  If select_features = TRUE, then acts as a multiplier for smoothness. Increase this beyond 1 to produce smoother models.

engine  A single character string specifying what computational engine to use for fitting.

Details

This function only defines what type of model is being fit. Once an engine is specified, the method to fit the model is also defined.

The model is not trained or fit until the fit.model_spec() function is used with the data.

fit.model_spec(), set_engine(), update(), mgcv engine details

Examples

show_engines("gen_additive_mod")
gen_additive_mod()

---

**glance.model_fit**  Construct a single row summary "glance" of a model, fit, or other object

Description

This method glances the model in a parsnip model object, if it exists.

Usage

```r
## S3 method for class 'model_fit'
glance(x, ...)
```

Arguments

- `x`  model or other R object to convert to single-row data frame
- `...`  other arguments passed to methods

Value

a tibble
**linear_reg**

**Description**

`linear_reg()` defines a model that can predict numeric values from predictors using a linear function.

There are different ways to fit this model. See the engine-specific pages for more details:

- `lm` (default)
- `glmnet`
- `stan`
- `spark`
- `keras`

More information on how `parsnip` is used for modeling is at https://www.tidymodels.org/.

**Usage**

```r
linear_reg(mode = "regression", engine = "lm", penalty = NULL, mixture = NULL)
```

**Arguments**

- **mode**
  A single character string for the type of model. The only possible value for this model is "regression".

- **engine**
  A single character string specifying what computational engine to use for fitting. Possible engines are listed below. The default for this model is "lm".

- **penalty**
  A non-negative number representing the total amount of regularization (specific engines only).

- **mixture**
  A number between zero and one (inclusive) that is the proportion of L1 regularization (i.e. lasso) in the model. When `mixture = 1`, it is a pure lasso model while `mixture = 0` indicates that ridge regression is being used (specific engines only).

**Details**

This function only defines what type of model is being fit. Once an engine is specified, the method to fit the model is also defined.

The model is not trained or fit until the `fit.model_spec()` function is used with the data.

logistic_reg

Examples

show_engines("linear_reg")

linear_reg()

logistic_reg

Logistic regression

Description

logistic_reg() defines a generalized linear model for binary outcomes. A linear combination of the predictors is used to model the log odds of an event.

There are different ways to fit this model. See the engine-specific pages for more details:

- glm (default)
- glmnet
- LiblineaR
- spark
- keras
- stan

More information on how parsnip is used for modeling is at https://www.tidymodels.org/.

Usage

logistic_reg(
  mode = "classification",
  engine = "glm",
  penalty = NULL,
  mixture = NULL
)

Arguments

mode

A single character string for the type of model. The only possible value for this model is "classification".

engine

A single character string specifying what computational engine to use for fitting. Possible engines are listed below. The default for this model is "glm".

penalty

A non-negative number representing the total amount of regularization (specific engines only). For keras models, this corresponds to purely L2 regularization (aka weight decay) while the other models can be either or a combination of L1 and L2 (depending on the value of mixture).

mixture

A number between zero and one (inclusive) that is the proportion of L1 regularization (i.e. lasso) in the model. When mixture = 1, it is a pure lasso model while mixture = 0 indicates that ridge regression is being used. (specific engines only). For LiblineaR models, mixture must be exactly 0 or 1 only.
Details

This function only defines what type of model is being fit. Once an engine is specified, the method to fit the model is also defined.

The model is not trained or fit until the `fit.model_spec()` function is used with the data.

References

https://www.tidymodels.org, Tidy Models with R

See Also

`fit.model_spec()`, `set_engine()`, `update()`, `glm engine details`, `glmnet engine details`, `LiblineaR engine details`, `spark engine details`, `keras engine details`, `stan engine details`

Examples

```r
show_engines("logistic_reg")

logistic_reg()
```

**mars**

*Multivariate adaptive regression splines (MARS)*

Description

`mars()` defines a generalized linear model that uses artificial features for some predictors. These features resemble hinge functions and the result is a model that is a segmented regression in small dimensions.

There are different ways to fit this model. See the engine-specific pages for more details:

- `earth` (default)

More information on how `parsnip` is used for modeling is at https://www.tidymodels.org/.

Usage

```r
mars(
  mode = "unknown",
  engine = "earth",
  num_terms = NULL,
  prod_degree = NULL,
  prune_method = NULL
)
```

Arguments

- **mode**
  A single character string for the prediction outcome mode. Possible values for this model are "unknown", "regression", or "classification".

- **engine**
  A single character string specifying what computational engine to use for fitting.
num_terms  The number of features that will be retained in the final model, including
the intercept.
prod_degree  The highest possible interaction degree.
prune_method  The pruning method.

Details
This function only defines what type of model is being fit. Once an engine is specified, the
method to fit the model is also defined.
The model is not trained or fit until the `fit.model_spec()` function is used with the data.

References
https://www.tidymodels.org, Tidy Models with R

See Also
`fit.model_spec()`, `set_engine()`, `update()`, `earth engine details`

Examples

```r
show_engines("mars")
mars(mode = "regression", num_terms = 5)
```

maybe_matrix  Fuzzy conversions

Description
These are substitutes for `as.matrix()` and `as.data.frame()` that leave a sparse matrix
as-is.

Usage

```r
maybe_matrix(x)
maybe_data_frame(x)
```

Arguments

- `x`  A data frame, matrix, or sparse matrix.

Value
A data frame, matrix, or sparse matrix.
**min_cols**

*Execution-time data dimension checks*

**Description**

For some tuning parameters, the range of values depend on the data dimensions (e.g. mtry). Some packages will fail if the parameter values are outside of these ranges. Since the model might receive resampled versions of the data, these ranges can’t be set prior to the point where the model is fit. These functions check the possible range of the data and adjust them if needed (with a warning).

**Usage**

```
min_cols(num_cols, source)

min_rows(num_rows, source, offset = 0)
```

**Arguments**

- `num_cols, num_rows`
  The parameter value requested by the user.
- `source`
  A data frame for the data to be used in the fit. If the source is named "data", it is assumed that one column of the data corresponds to an outcome (and is subtracted off).
- `offset`
  A number subtracted off of the number of rows available in the data.

**Value**

An integer (and perhaps a warning).

**Examples**

```
nearest_neighbor(neighbors= 100) %>%
  set_engine("kknn") %>%
  set_mode("regression") %>%
  translate()

library(ranger)
rand_forest(mtry = 2, min_n = 100, trees = 3) %>%
  set_engine("ranger") %>%
  set_mode("regression") %>%
  fit(mpg ~ ., data = mtcars)
```
Description

`mlp()` defines a multilayer perceptron model (a.k.a. a single layer, feed-forward neural network).

There are different ways to fit this model. See the engine-specific pages for more details:

- `keras`
- `nnet` (default)

More information on how `parsnip` is used for modeling is at [https://www.tidymodels.org/](https://www.tidymodels.org/).

Usage

```r
mlp(
  mode = "unknown",
  engine = "nnet",
  hidden_units = NULL,
  penalty = NULL,
  dropout = NULL,
  epochs = NULL,
  activation = NULL
)
```

Arguments

- **mode**: A single character string for the prediction outcome mode. Possible values for this model are "unknown", "regression", or "classification".
- **engine**: A single character string specifying what computational engine to use for fitting.
- **hidden_units**: An integer for the number of units in the hidden model.
- **penalty**: A non-negative numeric value for the amount of weight decay.
- **dropout**: A number between 0 (inclusive) and 1 denoting the proportion of model parameters randomly set to zero during model training.
- **epochs**: An integer for the number of training iterations.
- **activation**: A single character string denoting the type of relationship between the original predictors and the hidden unit layer. The activation function between the hidden and output layers is automatically set to either "linear" or "softmax" depending on the type of outcome. Possible values are: "linear", "softmax", "relu", and "elu"

Details

This function only defines what type of model is being fit. Once an engine is specified, the `method` to fit the model is also defined.

The model is not trained or fit until the `fit.model.spec()` function is used with the data.

model_fit  Model Fit Object Information

Description

An object with class "model_fit" is a container for information about a model that has been fit to the data.

Details

The main elements of the object are:

- \( \hat{\text{lvl}} \): A vector of factor levels when the outcome is a factor. This is NULL when the outcome is not a factor vector.
- \( \hat{\text{spec}} \): A model_spec object.
- \( \hat{\text{fit}} \): The object produced by the fitting function.
- \( \hat{\text{preproc}} \): This contains any data-specific information required to process new a sample point for prediction. For example, if the underlying model function requires arguments \( x \) and \( y \) and the user passed a formula to fit, the \( \text{preproc} \) object would contain items such as the terms object and so on. When no information is required, this is NA.

As discussed in the documentation for model_spec, the original arguments to the specification are saved as quosures. These are evaluated for the model_fit object prior to fitting. If the resulting model object prints its call, any user-defined options are shown in the call preceded by a tilde (see the example below). This is a result of the use of quosures in the specification.

This class and structure is the basis for how \text{parsnip} stores model objects after seeing the data and applying a model.

Examples

# Keep the "x" matrix if the data are not too big.
spec_obj <- linear_reg() %%
  set_engine("lm", x = ifelse(.obs() < 500, TRUE, FALSE))
spec_obj

fit_obj <- fit(spec_obj, mpg ~ ., data = mtcars)
Description

An object with class "model_spec" is a container for information about a model that will be fit.

Details

The main elements of the object are:

- **args**: A vector of the main arguments for the model. The names of these arguments may be different from their counterparts in the underlying model function. For example, for a glmnet model, the argument name for the amount of the penalty is called "penalty" instead of "lambda" to make it more general and usable across different types of models (and to not be specific to a particular model function). The elements of args can vary(). If left to their defaults (NULL), the arguments will use the underlying model functions default value. As discussed below, the arguments in args are captured as quosures and are not immediately executed.

- ...: Optional model-function-specific parameters. As with args, these will be quosures and can be vary().

- **mode**: The type of model, such as "regression" or "classification". Other modes will be added once the package adds more functionality.

- **method**: This is a slot that is filled in later by the model's constructor function. It generally contains lists of information that are used to create the fit and prediction code as well as required packages and similar data.

- **engine**: This character string declares exactly what software will be used. It can be a package name or a technology type.

This class and structure is the basis for how parsnip stores model objects prior to seeing the data.

Argument Details

An important detail to understand when creating model specifications is that they are intended to be functionally independent of the data. While it is true that some tuning parameters are data dependent, the model specification does not interact with the data at all.

For example, most R functions immediately evaluate their arguments. For example, when calling mean(dat_vec), the object dat_vec is immediately evaluated inside of the function. parsnip model functions do not do this. For example, using

```r
rand_forest(mtry = ncol(mtcars) - 1)
```

does not execute ncol(mtcars) -1 when creating the specification. This can be seen in the output:
The model functions save the argument expressions and their associated environments (a.k.a. a quosure) to be evaluated later when either `fit.model_spec()` or `fit_xy.model_spec()` are called with the actual data.

The consequence of this strategy is that any data required to get the parameter values must be available when the model is fit. The two main ways that this can fail is if:

1. The data have been modified between the creation of the model specification and when the model fit function is invoked.
2. If the model specification is saved and loaded into a new session where those same data objects do not exist.

The best way to avoid these issues is to not reference any data objects in the global environment but to use data descriptors such as `.cols()`. Another way of writing the previous specification is

```r
rand_forest(mtry = .cols() - 1)
```

This is not dependent on any specific data object and is evaluated immediately before the model fitting process begins.

One less advantageous approach to solving this issue is to use quasiquotation. This would insert the actual R object into the model specification and might be the best idea when the data object is small. For example, using

```r
rand_forest(mtry = ncol(!!mtcars) - 1)
```

would work (and be reproducible between sessions) but embeds the entire mtcars data set into the `mtry` expression:

```r
> rand_forest(mtry = ncol(!!mtcars) - 1)
Random Forest Model Specification (unknown)
Main Arguments:
mtry = ncol(structure(list(Sepal.Length = c(5.1, 4.9, 4.7, 4.6, 5, <snip>
```

However, if there were an object with the number of columns in it, this wouldn’t be too bad:

```r
> mtry_val <- ncol(mtcars) - 1
> mtry_val
[1] 10
> rand_forest(mtry = !!mtry_val)
Random Forest Model Specification (unknown)
Main Arguments:
mtry = 10
```

More information on quosures and quasiquotation can be found at [https://tidyeval.tidyverse.org](https://tidyeval.tidyverse.org).
multinom_reg

Description

multinom_reg() defines a model that uses linear predictors to predict multiclass data using the multinomial distribution.

There are different ways to fit this model. See the engine-specific pages for more details:

- glmnet
- spark
- keras
- nnet (default)

More information on how parsnip is used for modeling is at https://www.tidymodels.org/.

Usage

```r
multinom_reg(
  mode = "classification",
  engine = "nnet",
  penalty = NULL,
  mixture = NULL
)
```

Arguments

- **mode** A single character string for the type of model. The only possible value for this model is "classification".
- **engine** A single character string specifying what computational engine to use for fitting. Possible engines are listed below. The default for this model is "nnet".
- **penalty** A non-negative number representing the total amount of regularization (specific engines only). For keras models, this corresponds to purely L2 regularization (aka weight decay) while the other models can be a combination of L1 and L2 (depending on the value of mixture).
- **mixture** A number between zero and one (inclusive) that is the proportion of L1 regularization (i.e. lasso) in the model. When mixture = 1, it is a pure lasso model while mixture = 0 indicates that ridge regression is being used. (specific engines only).

Details

This function only defines what type of model is being fit. Once an engine is specified, the method to fit the model is also defined.

The model is not trained or fit until the fit.model_spec() function is used with the data.

multi_predict

Model predictions across many sub-models

Description

For some models, predictions can be made on sub-models in the model object.

Usage

multi_predict(object, ...)

## Default S3 method:
multi_predict(object, ...)

## S3 method for class "_xgb.Booster"
multi_predict(object, new_data, type = NULL, trees = NULL, ...)

## S3 method for class "_C5.0"
multi_predict(object, new_data, type = NULL, trees = NULL, ...)

## S3 method for class "_elnet"
multi_predict(object, new_data, type = NULL, penalty = NULL, ...)

## S3 method for class "_lognet"
multi_predict(object, new_data, type = NULL, penalty = NULL, ...)

## S3 method for class "_earth"
multi_predict(object, new_data, type = NULL, num_terms = NULL, ...)

## S3 method for class "_multnet"
multi_predict(object, new_data, type = NULL, penalty = NULL, ...)

## S3 method for class "_train.kknn"
multi_predict(object, new_data, type = NULL, neighbors = NULL, ...)

Arguments

- **object**: A `model_fit` object.
- **...**: Optional arguments to pass to `predict.model_fit(type = "raw")` such as `type`.
- **new_data**: A rectangular data object, such as a data frame.

See Also

`fit.model_spec()`, `set_engine()`, `update()`, `glmnet engine details`, `spark engine details`, `keras engine details`, `nnet engine details`
nearest_neighbor

**Value**

A tibble with the same number of rows as the data being predicted. There is a list-column named .pred that contains tibbles with multiple rows per sub-model. Note that, within the tibbles, the column names follow the usual standard based on prediction type (i.e. .pred_class for type = "class" and so on).

**Description**

nearest_neighbor() defines a model that uses the K most similar data points from the training set to predict new samples.

There are different ways to fit this model. See the engine-specific pages for more details:

- **kknn** (default)

More information on how parsnip is used for modeling is at https://www.tidymodels.org/.

**Usage**

nearest_neighbor(
  mode = "unknown",
  engine = "kknn",
  neighbors = NULL,
  weight_func = NULL,
  dist_power = NULL
)

**Arguments**

- **mode**
  A single character string for the prediction outcome mode. Possible values for this model are "unknown", "regression", or "classification".

- **engine**
  A single character string specifying what computational engine to use for fitting.

- **neighbors**
  A single integer for the number of neighbors to consider (often called k). For **kknn**, a value of 5 is used if neighbors is not specified.

- **weight_func**
  A single character for the type of kernel function used to weight distances between samples. Valid choices are: "rectangular", "triangular", "epanechnikov", "biweight", "triweight", "cos", "inv", "gaussian", "rank", or "optimal".

- **dist_power**
  A single number for the parameter used in calculating Minkowski distance.
null_model

null_model

Description

null_model() defines a simple, non-informative model. It doesn’t have any main arguments.

Usage

null_model(mode = "classification")

Arguments

mode A single character string for the prediction outcome mode. Possible values for this model are "unknown", "regression", or "classification".

Details

The model can be created using the fit() function using the following engines:

- R: "parsnip"

Engine Details

Engines may have pre-set default arguments when executing the model fit call. For this type of model, the template of the fit calls are below:

parsnip:

null_model() %>%
  set_engine("parsnip") %>%
  set_mode("regression") %>%
  translate()
## Model Specification (regression)

## Computational engine: parsnip

## Model fit template:
## `nullmodel(x = missing_arg(), y = missing_arg())`

```
null_model() %>%
  set_engine("parsnip") %>%
  set_mode("classification") %>%
  translate()
```

## Model Specification (classification)

## Computational engine: parsnip

## Model fit template:
## `nullmodel(x = missing_arg(), y = missing_arg())`

See Also

- `fit.model_spec()`

Examples

```
null_model(mode = "regression")
```

---

**parsnip_addin**

Start an RStudio Addin that can write model specifications

**Description**

`parsnip_addin()` starts a process in the RStudio IDE Viewer window that allows users to write code for `parsnip` model specifications from various R packages. The new code is written to the current document at the location of the cursor.

**Usage**

`parsnip_addin()`

---

**rand_forest**

Random forest
Description

`rand_forest()` defines a model that creates a large number of decision trees, each independent of the others. The final prediction uses all predictions from the individual trees and combines them.

There are different ways to fit this model. See the engine-specific pages for more details:

- `ranger` (default)
- `randomForest`
- `spark`

More information on how `parsnip` is used for modeling is at [https://www.tidymodels.org/](https://www.tidymodels.org/).

Usage

```r
rand_forest(
  mode = "unknown",
  engine = "ranger",
  mtry = NULL,
  trees = NULL,
  min_n = NULL
)
```

Arguments

- **mode**: A single character string for the prediction outcome mode. Possible values for this model are "unknown", "regression", or "classification".
- **engine**: A single character string specifying what computational engine to use for fitting.
- **mtry**: An integer for the number of predictors that will be randomly sampled at each split when creating the tree models.
- **trees**: An integer for the number of trees contained in the ensemble.
- **min_n**: An integer for the minimum number of data points in a node that are required for the node to be split further.

Details

This function only defines what type of model is being fit. Once an engine is specified, the method to fit the model is also defined.

The model is not trained or fit until the `fit.model_spec()` function is used with the data.

Examples

```r
show_engines("rand_forest")
rand_forest(mode = "classification", trees = 2000)
```

---

**repair_call**  
*Repair a model call object*

**Description**

When the user passes a formula to `fit()` and the underlying model function uses a formula, the call object produced by `fit()` may not be usable by other functions. For example, some arguments may still be quosures and the `data` portion of the call will not correspond to the original data.

**Usage**

```r
repair_call(x, data)
```

**Arguments**

- `x`: A fitted `parsnip` model. An error will occur if the underlying model does not have a `call` element.
- `data`: A data object that is relevant to the call. In most cases, this is the data frame that was given to `parsnip` for the model fit (i.e., the training set data). The name of this data object is inserted into the call.

**Details**

`repair_call()` can adjust the model object's call to be usable by other functions and methods.

**Value**

A modified `parsnip` fitted model.

**Examples**

```r
fitted_model <-
  linear_reg() %>%
  set_engine("lm", model = TRUE) %>%
  fit(mpg ~ ., data = mtcars)

# In this call, note that `data` is not `mtcars` and the `model = "TRUE"`
# indicates that the `model` argument is an `rlang` quosure.
fitted_model$fit$call

# All better:
repair_call(fitted_model, mtcars)$fit$call
```
Determine required packages for a model

**Usage**

```
req_pkgs(x, ...)
```

## S3 method for class 'model_spec'
```
req_pkgs(x, ...)
```

## S3 method for class 'model_fit'
```
req_pkgs(x, ...)
```

## S3 method for class 'model_spec'
```
required_pkgs(x, ...)
```

## S3 method for class 'model_fit'
```
required_pkgs(x, ...)
```

**Arguments**

- `x` A model specification or fit.
- `...` Not used.

**Details**

For a model specification, the engine must be set. The list produced by `req_pkgs()` does not include the `parsnip` package while `required_pkgs()` does.

**Value**

A character string of package names (if any).

**Examples**

```r
should_fail <- try(req_pkgs(linear_reg()), silent = TRUE)
should_fail

linear_reg() %>%
  set_engine("glmnet") %>%
  req_pkgs()

linear_reg() %>%
  set_engine("lm") %>%
  fit(mpg ~ ., data = mtcars) %>%
  req_pkgs()
```
Description

`set_args()` can be used to modify the arguments of a model specification while `set_mode()` is used to change the model's mode.

Usage

- `set_args(object, ...)`
- `set_mode(object, mode)`

Arguments

- `object`: A model specification.
- `...`: One or more named model arguments.
- `mode`: A character string for the model type (e.g., "classification" or "regression")

Details

- `set_args()` will replace existing values of the arguments.

Value

An updated model object.

Examples

```
rand_forest()

rand_forest() %>%
  set_args(mtry = 3, importance = TRUE) %>%
  set_mode("regression")
```

Description

`set_engine()` is used to specify which package or system will be used to fit the model, along with any arguments specific to that software.

Usage

- `set_engine(object, engine, ...)`
show_engines

Arguments

object
A model specification.

engine
A character string for the software that should be used to fit the model. This is highly dependent on the type of model (e.g. linear regression, random forest, etc.).

... Any optional arguments associated with the chosen computational engine. These are captured as quosures and can be varying().

Value
An updated model specification.

Examples

# First, set general arguments using the standardized names
mod <-
  logistic_reg(penalty = 0.01, mixture = 1/3) %>%
# now say how you want to fit the model and another other options
  set_engine("glmnet", nlambda = 10)
  translate(mod, engine = "glmnet")

show_engines(x)

Description

The possible engines for a model can depend on what packages are loaded. Some parsnip-adjacent packages add engines to existing models. For example, the multilevelmod package adds additional engines for the linear_reg() model and these are not available unless multilevelmod is loaded.

Usage

show_engines(x)

Arguments

x 
The name of a parsnip model (e.g., "linear_reg", "mars", etc.)

Value

A tibble.

Examples

show_engines("linear_reg")
**svm_linear**

**Linear support vector machines**

**Description**

`svm_linear()` defines a support vector machine model. For classification, the model tries to maximize the width of the margin between classes. For regression, the model optimizes a robust loss function that is only affected by very large model residuals.

This SVM model uses a linear function to create the decision boundary or regression line.

There are different ways to fit this model. See the engine-specific pages for more details:

- *LiblineaR* (default)
- *kernlab*

More information on how *parsnip* is used for modeling is at [https://www.tidymodels.org](https://www.tidymodels.org).

**Usage**

```r
svm_linear(mode = "unknown", engine = "LiblineaR", cost = NULL, margin = NULL)
```

**Arguments**

- **mode**
  - A single character string for the prediction outcome mode. Possible values for this model are "unknown", "regression", or "classification".

- **engine**
  - A single character string specifying what computational engine to use for fitting.

- **cost**
  - A positive number for the cost of predicting a sample within or on the wrong side of the margin

- **margin**
  - A positive number for the epsilon in the SVM insensitive loss function (regression only)

**Details**

This function only defines what type of model is being fit. Once an engine is specified, the method to fit the model is also defined.

The model is not trained or fit until the `fit.model_spec()` function is used with the data.

**References**

[https://www.tidymodels.org](https://www.tidymodels.org), *Tidy Models with R*

**See Also**

`fit.model_spec()`, `set_engine()`, `update()`, `LiblineaR` engine details, `kernlab` engine details

**Examples**

```r
show_engines("svm_linear")
```

```r
svm_linear(mode = "classification")
```
**Description**

`svm_poly()` defines a support vector machine model. For classification, the model tries to maximize the width of the margin between classes. For regression, the model optimizes a robust loss function that is only affected by very large model residuals.

This SVM model uses a nonlinear function, specifically a polynomial function, to create the decision boundary or regression line.

There are different ways to fit this model. See the engine-specific pages for more details:

- `kernlab` (default)

More information on how `parsnip` is used for modeling is at [https://www.tidymodels.org/](https://www.tidymodels.org/).

**Usage**

```r
svm_poly(
  mode = "unknown",
  engine = "kernlab",
  cost = NULL,
  degree = NULL,
  scale_factor = NULL,
  margin = NULL
)
```

**Arguments**

- `mode` A single character string for the prediction outcome mode. Possible values for this model are "unknown", "regression", or "classification".
- `engine` A single character string specifying what computational engine to use for fitting.
- `cost` A positive number for the cost of predicting a sample within or on the wrong side of the margin.
- `degree` A positive number for polynomial degree.
- `scale_factor` A positive number for the polynomial scaling factor.
- `margin` A positive number for the epsilon in the SVM insensitive loss function (regression only)

**Details**

This function only defines what type of model is being fit. Once an engine is specified, the `method` to fit the model is also defined.

The model is not trained or fit until the `fit.model_spec()` function is used with the data.

---

Usage

svm_rbf(
  mode = "unknown",
  engine = "kernlab",
  cost = NULL,
  rbf_sigma = NULL,
  margin = NULL
)

Arguments

mode A single character string for the prediction outcome mode. Possible values for this model are "unknown", "regression", or "classification".

engine A single character string specifying what computational engine to use for fitting. Possible engines are listed below. The default for this model is "kernlab".

cost A positive number for the cost of predicting a sample within or on the wrong side of the margin

rbf_sigma A positive number for radial basis function.

margin A positive number for the epsilon in the SVM insensitive loss function (regression only)
Details
This function only defines what *type* of model is being fit. Once an engine is specified, the *method* to fit the model is also defined.

The model is not trained or fit until the `fit.model_spec()` function is used with the data.

tidy.model_fit: Turn a parsnip model object into a tidy tibble

Description
This method tidies the model in a parsnip model object, if it exists.

Usage

```r
## S3 method for class 'model_fit'
tidy(x, ...)
```

Arguments

- `x` An object to be converted into a tidy `tibble::tibble()`.
- `...` Additional arguments to tidying method.

Value

a tibble
translate Resolve a Model Specification for a Computational Engine

Description

translate() will translate a model specification into a code object that is specific to a particular engine (e.g. R package). It translates generic parameters to their counterparts.

Usage

translate(x, ...)

## Default S3 method:
translate(x, engine = x$engine, ...)

Arguments

x A model specification.
...
Not currently used.
engine The computational engine for the model (see ?set_engine).

Details

translate() produces a template call that lacks the specific argument values (such as data, etc). These are filled in once fit() is called with the specifics of the data for the model. The call may also include varying arguments if these are in the specification.

It does contain the resolved argument names that are specific to the model fitting function/engine.

This function can be useful when you need to understand how parsnip goes from a generic model specific to a model fitting function.

Note: this function is used internally and users should only use it to understand what the underlying syntax would be. It should not be used to modify the model specification.

Examples

lm_spec <- linear_reg(penalty = 0.01)

# "penalty" is translates to "lambda"
translate(lm_spec, engine = "glmnet")

# "penalty" not applicable for this model.
translate(lm_spec, engine = "lm")

# "penalty" is translates to "reg_param"
translate(lm_spec, engine = "spark")

# with a placeholder for an unknown argument value:
translate(linear_reg(penalty = varying(), mixture = varying()), engine = "glmnet")
update.boost_tree  Update a model specification

Description

If parameters of a model specification need to be modified, update() can be used in lieu of recreating the object from scratch.

Usage

```r
## S3 method for class 'boost_tree'
update(
  object,
  parameters = NULL,
  mtry = NULL,
  trees = NULL,
  min_n = NULL,
  tree_depth = NULL,
  learn_rate = NULL,
  loss_reduction = NULL,
  sample_size = NULL,
  stop_iter = NULL,
  fresh = FALSE,
  ...
)

## S3 method for class 'decision_tree'
update(
  object,
  parameters = NULL,
  cost_complexity = NULL,
  tree_depth = NULL,
  min_n = NULL,
  fresh = FALSE,
  ...
)

## S3 method for class 'gen_additive_mod'
update(
  object,
  select_features = NULL,
  adjust_deg_free = NULL,
  parameters = NULL,
  fresh = FALSE,
  ...
)

## S3 method for class 'linear_reg'
update(
  object,
  parameters = NULL,
  ...
update.boost_tree

penalty = NULL,

eighbors = NULL,
weight_func = NULL,
dist_power = NULL,
fresh = FALSE,
...
)

## S3 method for class 'proportional_hazards'
update(
  object,
  parameters = NULL,
  penalty = NULL,
  mixture = NULL,
  fresh = FALSE,
  ...
)

## S3 method for class 'rand_forest'
update(
  object,
  parameters = NULL,
  mtry = NULL,
  trees = NULL,
  min_n = NULL,
  fresh = FALSE,
  ...
)

## S3 method for class 'surv_reg'
update(object, parameters = NULL, dist = NULL, fresh = FALSE, ...)

## S3 method for class 'survival_reg'
update(object, parameters = NULL, dist = NULL, fresh = FALSE, ...)

## S3 method for class 'svm_linear'
update(
  object,
  parameters = NULL,
  cost = NULL,
  margin = NULL,
  fresh = FALSE,
  ...
)

## S3 method for class 'svm_poly'
update(
  object,
  parameters = NULL,
  cost = NULL,
  degree = NULL,
Arguments

**object**
A model specification.

**parameters**
A 1-row tibble or named list with *main* parameters to update. Use **either** `parameters` *or* the main arguments directly when updating. If the main arguments are used, these will supersede the values in `parameters`. Also, using engine arguments in this object will result in an error.

**mtry**
A number for the number (or proportion) of predictors that will be randomly sampled at each split when creating the tree models (specific engines only)

**trees**
An integer for the number of trees contained in the ensemble.

**min_n**
An integer for the minimum number of data points in a node that is required for the node to be split further.

**tree_depth**
An integer for the maximum depth of the tree (i.e. number of splits) (specific engines only).

**learn_rate**
A number for the rate at which the boosting algorithm adapts from iteration-to-iteration (specific engines only).

**loss_reduction**
A number for the reduction in the loss function required to split further (specific engines only).

**sample_size**
A number for the number (or proportion) of data that is exposed to the fitting routine. For `xgboost`, the sampling is done at each iteration while `C5.0` samples once during training.

**stop_iter**
The number of iterations without improvement before stopping (specific engines only).

**fresh**
A logical for whether the arguments should be modified in-place or replaced wholesale.

... Not used for `update()`.

**cost_complexity**
A positive number for the cost/complexity parameter (a.k.a. $C_p$) used by CART models (specific engines only).
select_features

   TRUE or FALSE. If TRUE, the model has the ability to eliminate a predictor
   (via penalization). Increasing adjust_deg_free will increase the likelihood
   of removing predictors.

adjust_deg_free

   If select_features = TRUE, then acts as a multiplier for smoothness. In-
   crease this beyond 1 to produce smoother models.

penalty

   A non-negative number representing the total amount of regularization
   (specific engines only).

mixture

   A number between zero and one (inclusive) that is the proportion of L1
   regularization (i.e. lasso) in the model. When mixture = 1, it is a pure
   lasso model while mixture = 0 indicates that ridge regression is being used
   (specific engines only).

num_terms

   The number of features that will be retained in the final model, including
   the intercept.

prod_degree

   The highest possible interaction degree.

prune_method

   The pruning method.

hidden_units

   An integer for the number of units in the hidden model.

dropout

   A number between 0 (inclusive) and 1 denoting the proportion of model
   parameters randomly set to zero during model training.

epochs

   An integer for the number of training iterations.

activation

   A single character string denoting the type of relationship between the
   original predictors and the hidden unit layer. The activation function
   between the hidden and output layers is automatically set to either "lin-
   ear" or "softmax" depending on the type of outcome. Possible values are:
   "linear", "softmax", "relu", and "elu"

neighbors

   A single integer for the number of neighbors to consider (often called k).
   For kkm, a value of 5 is used if neighbors is not specified.

weight_func

   A single character for the type of kernel function used to weight distances
   between samples. Valid choices are: "rectangular", "triangular", "epanechnikov",
   "biweight", "triweight", "cos", "inv", "gaussian", "rank", or "optimal".

dist_power

   A single number for the parameter used in calculating Minkowski distance.

dist

   A character string for the outcome distribution. "weibull" is the default.

cost

   A positive number for the cost of predicting a sample within or on the
   wrong side of the margin

margin

   A positive number for the epsilon in the SVM insensitive loss function
   (regression only)

degree

   A positive number for polynomial degree.

scale_factor

   A positive number for the polynomial scaling factor.

rbf_sigma

   A positive number for radial basis function.

Value

   An updated model specification.
Examples

```r
model <- boost_tree(mtry = 10, min_n = 3)
model
update(model, mtry = 1)
update(model, mtry = 1, fresh = TRUE)

param_values <- tibble::tibble(mtry = 10, tree_depth = 5)
model %>% update(param_values)
model %>% update(param_values, mtry = 3)

param_values$verbose <- 0
# Fails due to engine argument
# model %>% update(param_values)

model <- linear_reg(penalty = 10, mixture = 0.1)
model
update(model, penalty = 1)
update(model, penalty = 1, fresh = TRUE)
```

---

**varying_args.model_spec**

*Determine varying arguments*

**Description**

`varying_args()` takes a model specification or a recipe and returns a tibble of information on all possible varying arguments and whether or not they are actually varying.

**Usage**

```r
## S3 method for class 'model_spec'
varying_args(object, full = TRUE, ...)

## S3 method for class 'recipe'
varying_args(object, full = TRUE, ...)

## S3 method for class 'step'
varying_args(object, full = TRUE, ...)
```

**Arguments**

- `object` A `model_spec` or a `recipe`.
- `full` A single logical. Should all possible varying parameters be returned? If `FALSE`, then only the parameters that are actually varying are returned.
- `...` Not currently used.

**Details**

The `id` column is determined differently depending on whether a `model_spec` or a `recipe` is used. For a `model_spec`, the first class is used. For a `recipe`, the unique step `id` is used.
Value

A tibble with columns for the parameter name (name), whether it contains any varying value (varying), the id for the object (id), and the class that was used to call the method (type).

Examples

```r
# List all possible varying args for the random forest spec
rand_forest() %>% varying_args()

# mtry is now recognized as varying
rand_forest(mtry = varying()) %>% varying_args()

# Even engine specific arguments can vary
rand_forest() %>%
  set_engine("ranger", sample.fraction = varying()) %>%
  varying_args()

# List only the arguments that actually vary
rand_forest() %>%
  set_engine("ranger", sample.fraction = varying()) %>%
  varying_args(full = FALSE)

rand_forest() %>%
  set_engine(
    "randomForest",
    strata = Class,
    sampsize = varying()
  ) %>%
  varying_args()
```
