Package ‘pencal’

December 1, 2021

Title Penalized Regression Calibration (PRC)

Version 1.0.1

Description Computes penalized regression calibration (PRC), a statistical method that allows to predict survival from high-dimensional longitudinal predictors. PRC is described in Signorelli et al. (2021, <doi:10.1002/sim.9178>).

fitted_prclmm

Description

This list contains a fitted PRC LMM, where the CBOCP is computed using 50 cluster bootstrap samples. It is used to reduce the computing time in the example of the function performance_prc.

Usage

```r
data(fitted_prclmm)
```

Format

A list comprising step 2 and step 3 as obtained during the estimation of a PRC LMM.

Author(s)

Mirko Signorelli

References

See Also

```r

Examples

```r
data(fitted_prclmm)
ls(fitted_prclmm)
```
**fitted_prcmlpmm**

**A fitted PRC MLPMM**

**Description**

This list contains a fitted PRC MLPMM. It is used to reduce the computing time in the example of the function `survpred_prcmlpmm`.

**Usage**

```r
data(fitted_prcmlpmm)
```

**Format**

A list comprising step 2 and step 3 as obtained during the estimation of a PRC MLPMM.

**Author(s)**

Mirko Signorelli

**References**

**See Also**

`survpred_prcmlpmm`

**Examples**

```r
data(fitted_prcmlpmm)
ls(fitted_prcmlpmm)
```

---

**fit_lmms**

**Step 1 of PRC-LMM (estimation of the linear mixed models)**

**Description**

This function performs the first step for the estimation of the PRC-LMM model proposed in Signorelli et al. (2021).

**Usage**

```r
fit_lmms(y.names, fixefs, ranefs, long.data, surv.data, t.from.base, n.boots = 0, n.cores = 1, verbose = TRUE)
```
Arguments

- **y.names**: character vector with the names of the response variables which the LMMs have to be fitted to.
- **fixefs**: fixed effects formula for the model, example: ~ time.
- **ranefs**: random effects formula for the model, specified using the representation of random effect structures of the R package nlme.
- **long.data**: a data frame with the longitudinal predictors, comprehensive of a variable called id with the subject ids.
- **surv.data**: a data frame with the survival data and (if relevant) additional baseline covariates. surv.data should at least contain a subject id (called id), the time to event outcome (time), and binary event variable (event).
- **t.from.base**: name of the variable containing time from baseline in long.data.
- **n.boots**: number of bootstrap samples to be used in the cluster bootstrap optimism correction procedure (CBOCP). If 0, no bootstrapping is performed.
- **n.cores**: number of cores to use to parallelize the computation of the CBOCP procedure. If n.cores = 1 (default), no parallelization is done. Pro tip: you can use parallel::detectCores() to check how many cores are available on your computer.
- **verbose**: if TRUE (default and recommended value), information on the ongoing computations is printed in the console.

Value

A list containing the following objects:

- **call.info**: a list containing the following function call information: call, y.names, fixefs, ranefs;
- **lmm.fits.orig**: a list with the LMMs fitted on the original dataset (it should comprise as many LMMs as the elements of y.names are);
- **df.sanitized**: a sanitized version of the supplied long.data dataframe, without the longitudinal measurements that are taken after the event or after censoring;
- **n.boots**: number of bootstrap samples;
- **boot.ids**: a list with the ids of bootstrapped subjects (when n.boots > 0);
- **lms.fits.boot**: a list of lists, which contains the LMMs fitted on each bootstrapped datasets (when n.boots > 0).

Examples

# generate example data
set.seed(1234)
p = 4 # number of longitudinal predictors
simdata = simulate_prclmm_data(n = 100, p = p, p.relev = 2,
    seed = 123, t.values = c(0, 0.2, 0.5, 1, 1.5, 2))

# specify options for cluster bootstrap optimism correction
# procedure and for parallel computing
do.bootstrap = FALSE
# IMPORTANT: set do.bootstrap = TRUE to compute the optimism correction!
n.boots = ifelse(do.bootstrap, 100, 0)
parallelize = FALSE
# IMPORTANT: set parallelize = TRUE to speed computations up!
if (!parallelize) n.cores = 1
if (parallelize) {
    # identify number of available cores on your machine
    n.cores = parallel::detectCores()
    if (is.na(n.cores)) n.cores = 1
}

# step 1 of PRC-LMM: estimate the LMMs
y.names = paste('mark{1:p, sep = '
step1 = fit_lmms(y.names = y.names,
    fixefs = ~ age, ranefs = ~ age | id,
    long.data = simdata$long.data,
    surv.data = simdata$surv.data,
    t.from.base = t.from.base,
    n.boots = n.boots, n.cores = n.cores)
Arguments

y.names  a list with the names of the response variables which the MLPMMs have to be fitted to. Each element in the list contains all the items used to reconstruct a latent biological process of interest

fixefs  a fixed effects formula for the model, where the time variable (specified also in ranef.time) is included as first element and within the function contrast(). Examples: ~ contrast(age), ~ contrast(age) + group + treatment

ranef.time  a character with the name of the time variable for which to include a shared random slope

randint.items  logical: should item-specific random intercepts be included in the MLCMMs? Default is TRUE. It can also be a vector, with different values for different elements of y.names

long.data  a data frame with the longitudinal predictors, comprehensive of a variable called id with the subject ids

surv.data  a data frame with the survival data and (if relevant) additional baseline covariates. surv.data should at least contain a subject id (called id), the time to event outcome (time), and binary event variable (event)

t.from.base  name of the variable containing time from baseline in long.data

n.boots  number of bootstrap samples to be used in the cluster bootstrap optimism correction procedure (CBOCP). If 0, no bootstrapping is performed

n.cores  number of cores to use to parallelize the computation of the CBOCP procedure. If ncores = 1 (default), no parallelization is done. Pro tip: you can use parallel::detectCores() to check how many cores are available on your computer

verbose  if TRUE (default and recommended value), information on the ongoing computations is printed in the console

maxiter  maximum number of iterations to use when calling the function multlcmm. Default is 100

conv  a vector containing the three convergence criteria (convB, convL and convG) to use when calling the function multlcmm. Default is c(1e-3, 1e-3, 1e-3)

lcmm.warnings  logical. If TRUE, a warning is printed every time the (strict) convergence criteria of the multlcmm function are not met. Default is FALSE

Details

This function is essentially a wrapper of the multlcmm function that has the goal of simplifying the estimation of several MLPMMs. In general, ensuring convergence of the algorithm implemented in multlcmm is sometimes difficult, and it is hard to write a function that can automatically solve these convergence problems. fit_mlpmms returns a warning when estimation did not converge for one or more MLPMMs. If this happens, try to change the convergence criteria in conv or the relevant randint.items value. If doing this doesn’t solve the problem, it is recommended to re-estimate the specific MLPMMs for which estimation didn’t converge directly with multlcmm, trying to manually solve the convergence issues.
Value

A list containing the following objects:

- `call.info`: a list containing the following function call information: `call`, `y.names`, `fixefs`, `ranef.time`, `randint.items`;
- `mlpmm.fits.orig`: a list with the MLPMMs fitted on the original dataset (it should comprise as many MLPMMs as the elements of `y.names` are);
- `df.sanitized`: a sanitized version of the supplied `long.data` dataframe, without the longitudinal measurements that are taken after the event or after censoring;
- `n.boots`: number of bootstrap samples;
- `boot.ids`: a list with the ids of bootstrapped subjects (when `n.boots > 0`);
- `mlpmm.fits.boot`: a list of lists, which contains the MLPMMs fitted on each bootstrapped datasets (when `n.boots > 0`).

                   n.boots = n.boots, n.cores = n.cores)

## fit_prclmm

Step 3 of PRC-LMM (estimation of the penalized Cox model(s))

Description

This function performs the third step for the estimation of the PRC-LMM model proposed in SIGNORELLI et al. (2021)

Usage

fit_prclmm(object, surv.data, baseline.covs = NULL, penalty = "ridge",
            standardize = TRUE, pfac.base.covs = 0, n.alpha.elnet = 11,
            n.folds.elnet = 5, n.cores = 1, verbose = TRUE)

Arguments

object the output of step 2 of the PRC-LMM procedure, as produced by the summarize_lmms function

surv.data a data frame with the survival data and (if relevant) additional baseline covariates. surv.data should at least contain a subject id (called id), the time to event outcome (time), and binary event variable (event)

baseline.covs a formula specifying the variables (e.g., baseline age) in surv.data that should be included as baseline covariates in the penalized Cox model. Example: baseline.covs = ~ baseline.age. Default is NULL

penalty the type of penalty function used for regularization. Default is 'ridge', other possible values are 'elasticnet' and 'lasso'

standardize logical argument: should the predicted random effects be standardized when included in the penalized Cox model? Default is TRUE

pfac.base.covs a single value, or a vector of values, indicating whether the baseline covariates (if any) should be penalized (1) or not (0). Default is pfac.base.covs = 0 (no penalization of all baseline covariates)
**Value**

A list containing the following objects:

- call: the function call
- pcox.orig: the penalized Cox model fitted on the original dataset;
- surv.data: the supplied survival data (ordered by subject id)
- n.boots: number of bootstrap samples;
- boot.ids: a list with the ids of bootstrapped subjects (when n.boots > 0);
- pcox.boot: a list where each element is a fitted penalized Cox model for a given bootstrap sample (when n.boots > 0).

fit_prcmlpmm

Step 3 of PRC-MLPMM (estimation of the penalized Cox model(s))

Description
This function performs the third step for the estimation of the PRC-MLPMM model proposed in Signorelli et al. (2021)

Usage
fit_prcmlpmm(object, surv.data, baseline.covs = NULL, include.b0s = TRUE,
  penalty = c("ridge", standardize = TRUE, pfac.base.covs = 0,
  n.alpha.elnet = 11, n.folds.elnet = 5, n.cores = 1, verbose = TRUE)

Arguments
object the output of step 2 of the PRC-MLPMM procedure, as produced by the summarize_mlpmms
  function
surv.data     a data frame with the survival data and (if relevant) additional baseline covariates. surv.data should at least contain a subject id (called id), the time to event outcome (time), and binary event variable (event)

baseline.covs  a formula specifying the variables (e.g., baseline age) in surv.data that should be included as baseline covariates in the penalized Cox model. Example: baseline.covs = ' ~ baseline.age'. Default is NULL

include.b0s logical. If TRUE, the PRC-MLPMM(U+B) model is estimated; if FALSE, the PRC-MLPMM(U) model is estimated. See Signorelli et al. (2021) for details

penalty the type of penalty function used for regularization. Default is 'ridge', other possible values are 'elasticnet' and 'lasso'

standardize logical argument: should the predicted random effects be standardized when included in the penalized Cox model? Default is TRUE

pfac.base.covs a single value, or a vector of values, indicating whether the baseline covariates (if any) should be penalized (1) or not (0). Default is pfac.base.covs = 0 (no penalization of all baseline covariates)

n.alpha.elnet number of alpha values for the two-dimensional grid of tuning parameters in elasticnet. Only relevant if penalty = 'elasticnet'. Default is 11, so that the resulting alpha grid is c(1, 0.9, 0.8, ..., 0.1, 0)

n.folds.elnet number of folds to be used for the selection of the tuning parameter in elasticnet. Only relevant if penalty = 'elasticnet'. Default is 5

n.cores number of cores to use to parallelize the computation of the cluster bootstrap optimism correction procedure. If ncores = 1 (default), no parallelization is done. Pro tip: you can use parallel::detectCores() to check how many cores are available on your computer

verbose if TRUE (default and recommended value), information on the ongoing computations is printed in the console

Value

A list containing the following objects:

- call: the function call
- pcox.orig: the penalized Cox model fitted on the original dataset;
- surv.data: the supplied survival data (ordered by subject id)
- n.boots: number of bootstrap samples;
- boot.ids: a list with the ids of bootstrapped subjects (when n.boots > 0);
- pcox.boot: a list where each element is a fitted penalized Cox model for a given bootstrap sample (when n.boots > 0).

    baseline.covs = ~ baseline.age,
Description

This function estimates a penalized Cox model where only baseline covariates are included as predictors, and then computes a bootstrap optimism correction procedure that is used to validate the predictive performance of the model.

Usage

pencox_baseline(data, formula, penalty = "ridge", standardize = TRUE, penalty.factor = 1, n.alpha.elnet = 11, n.folds.elnet = 5, n.boots = 0, n.cores = 1, verbose = TRUE)

Arguments

data: a data frame with one row for each subject. It should at least contain a subject id (called id), the time to event outcome (time), and the binary censoring indicator (event), plus at least one covariate to be included in the linear predictor.

formula: a formula specifying the variables in data to include as predictors in the penalized Cox model.

penalty: the type of penalty function used for regularization. Default is 'ridge', other possible values are 'elasticnet' and 'lasso'.

standardize: logical argument: should the predicted random effects be standardized when included in the penalized Cox model? Default is TRUE.

penalty.factor: a single value, or a vector of values, indicating whether the covariates (if any) should be penalized (1) or not (0). Default is penalty.factor = 1.

n.alpha.elnet: number of alpha values for the two-dimensional grid of tuning parameters in elasticnet. Only relevant if penalty = 'elasticnet'. Default is 11, so that the resulting alpha grid is c(1, 0.9, 0.8, ..., 0.1, 0).

n.folds.elnet: number of folds to be used for the selection of the tuning parameter in elasticnet. Only relevant if penalty = 'elasticnet'. Default is 5.

n.boots: number of bootstrap samples to be used in the bootstrap optimism correction procedure. If 0, no bootstrapping is performed.

n.cores: number of cores to use to parallelize the computation of the bootstrap optimism correction procedure. If ncores = 1 (default), no parallelization is performed. Pro tip: you can use parallel::detectCores() to check how many cores are available on your computer.

verbose: if TRUE (default and recommended value), information on the ongoing computations is printed in the console.
Value

A list containing the following objects:

- call: the function call
- pcox.orig: the penalized Cox model fitted on the original dataset;
- surv.data: a data frame with the survival data
- X.orig: a data frame with the design matrix used to estimate the Cox model
- n.boots: number of bootstrap samples;
- boot.ids: a list with the ids of bootstrapped subjects (when n.boots > 0);
- pcox.boot: a list where each element is a fitted penalized Cox model for a given bootstrap sample (when n.boots > 0).

**performance_pencox_baseline**

Predictive performance of the penalized Cox model with baseline covariates

Description

This function computes the naive and optimism-corrected measures of performance (C index and time-dependent AUC) for a penalized Cox model with baseline covariates as presented in Signorelli et al. (2021). The optimism correction is a bootstrap optimism correction procedure.

Usage

```r
performance_pencoxBaseline(fitted_pencox, times = 1, n.cores = 1, verbose = TRUE)
```

Arguments

- `fitted_pencox`: the output of `pencox_baseline`
- `times`: numeric vector with the time points at which to estimate the time-dependent AUC
- `n.cores`: number of cores to use to parallelize the computation of the CBOCP procedure. If `n.cores = 1` (default), no parallelization is done. Pro tip: you can use `parallel::detectCores()` to check how many cores are available on your computer
- `verbose`: if `TRUE` (default and recommended value), information on the ongoing computations is printed in the console

Value

A list containing the following objects:

- `call`: the function call;
- `concordance`: a data frame with the naive and optimism-corrected estimates of the concordance (C) index;
- `tdAUC`: a data frame with the naive and optimism-corrected estimates of the time-dependent AUC at the desired time points.

Predictive performance of the PRC-LMM and PRC-MLPMM models

Description

This function computes the naive and optimism-corrected measures of performance (C index and time-dependent AUC) for the PRC models proposed in Signorelli et al. (2021). The optimism correction is computed based on a cluster bootstrap optimism correction procedure (CBOCP).

Usage

performance_prc(step2, step3, times = 1, n.cores = 1, verbose = TRUE)

Arguments

- **step2**: the output of either `summarize_lmms` or `summarize_mlpmms` (step 2 of the estimation of PRC)
- **step3**: the output of `fit_prclmm` or `fit_prcmlpmm` (step 3 of PRC)
- **times**: numeric vector with the time points at which to estimate the time-dependent AUC
- **n.cores**: number of cores to use to parallelize the computation of the CBOCP procedure. If `ncores = 1` (default), no parallelization is done. Pro tip: you can use `parallel::detectCores()` to check how many cores are available on your computer
- **verbose**: if TRUE (default and recommended value), information on the ongoing computations is printed in the console

Value

A list containing the following objects:

- **call**: the function call;
- **concordance**: a data frame with the naive and optimism-corrected estimates of the concordance (C) index;
- **tdAUC**: a data frame with the naive and optimism-corrected estimates of the time-dependent AUC at the desired time points.

References

**simulate_prclmm_data**  
Simulate data that can be used to fit the PRC-LMM model

**Description**

This function allows to simulate a survival outcome from longitudinal predictors. Specifically, the longitudinal predictors are simulated from linear mixed models (LMMs), and the survival outcome from a Weibull model where the time to event depends on the random effects from the LMMs. It is an implementation of the simulation method used in Signorelli et al. (2021)

**Usage**

```r
simulate_prclmm_data(n = 100, p = 10, p.relev = 4, lambda = 0.2,  
nu = 2, seed = 1, base.age.range = c(3, 5), cens.range = c(0.5, 10),  
t.values = c(0, 0.5, 1, 2))
```
Arguments

- **n**: sample size
- **p**: number of longitudinal outcomes
- **p.relev**: number of longitudinal outcomes that are associated with the survival outcome (min: 1, max: p)
- **lambda**: Weibull location parameter, positive
- **nu**: Weibull scale parameter, positive
- **seed**: random seed (defaults to 1)
- **base.age.range**: range for age at baseline (set it equal to c(0, 0) if you want all subjects to enter the study at the same age)
- **cens.range**: range for censoring times
- **t.values**: vector specifying the time points at which longitudinal measurements are collected (NB: for simplicity, this function assumes a balanced designed; however, pencal is designed to work both with balanced and with unbalanced designs!)

Value

A list containing the following elements:

- a dataframe `long.data` with data on the longitudinal predictors, comprehensive of a subject id (id), baseline age (base.age), time from baseline (t.from.base) and the longitudinal biomarkers;
- a dataframe `surv.data` with the survival data: a subject id (id), baseline age (baseline.age), the time to event outcome (time) and a binary vector (event) that is 1 if the event is observed, and 0 in case of right-censoring;
- `perc.cens` the proportion of censored individuals in the simulated dataset.

Examples

```r
# generate example data
simdata = simulate_prclmm_data(n = 20, p = 10,
                              lambda = 4, seed = 1)
# view the longitudinal markers:
library(ptmixed)
make.spaghetti(x = age, y = marker1,
               id = id, group = id,
               data = simdata$long.data,
```

```
simulate_prcmlpmm_data

Simulate data that can be used to fit the PRC-LMM model

Description

This function allows to simulate a survival outcome from longitudinal predictors. Specifically, the longitudinal predictors are simulated from multivariate latent process mixed models (MLPMMs), and the survival outcome from a Weibull model where the time to event depends on the random effects from the MLPMMs. It is an implementation of the simulation method used in Signorelli et al. (2021)

Usage

simulate_prcmlpmm_data(n = 100, p = 5, p.relev = 2, n.items = c(3, 2, 3, 4, 1), type = "u", lambda = 0.2, nu = 2, seed = 1, base.age.range = c(3, 5), cens.range = c(0.5, 10), t.values = c(0, 0.5, 1, 2))

Arguments

- **n**: sample size
- **p**: number of longitudinal latent processes
- **p.relev**: number of latent processes that are associated with the survival outcome (min: 1, max: p)
- **n.items**: number of items that are observed for each latent process of interest. It must be either a scalar, or a vector of length p
- **type**: the type of relation between the longitudinal outcomes and survival time. Two values can be used: 'u' refers to the PRC-MLPMM(U) model, and 'u+b' to the PRC-MLPMM(U+B) model presented in Section 2.3 of Signorelli et al. (2021). See the article for the mathematical details
- **lambda**: Weibull location parameter, positive
- **nu**: Weibull scale parameter, positive
- **seed**: random seed (defaults to 1)
simulate_prcmlpmm_data

base.age.range  range for age at baseline (set it equal to c(0, 0) if you want all subjects to enter
the study at the same age)
cens.range      range for censoring times
t.values        vector specifying the time points at which longitudinal measurements are col-
                lected (NB: for simplicity, this function assumes a balanced designed; however,
                pencal is designed to work both with balanced and with unbalanced designs!)

Value

A list containing the following elements:

- a dataframe `long.data` with data on the longitudinal predictors, comprehensive of a subject
  id (`id`), baseline age (`base.age`), time from baseline (`t.from.base`) and the longitudinal
  biomarkers;
- a dataframe `surv.data` with the survival data: a subject id (`id`), baseline age (`baseline.age`),
  the time to event outcome (`time`) and a binary vector (`event`) that is 1 if the event is observed,
  and 0 in case of right-censoring;
- `perc.cens` the proportion of censored individuals in the simulated dataset.

legend.inset = -1)

# proportion of censored subjects
simulate_t_weibull

Generate survival data from a Weibull model

Description
This function implements the algorithm proposed by Bender et al. (2005) to simulate survival times from a Weibull model.

Usage
simulate_t_weibull(n, lambda, nu, X, beta, seed = 1)

Arguments
- n: sample size
- lambda: Weibull location parameter, positive
- nu: Weibull scale parameter, positive
- X: design matrix (n rows, p columns)
- beta: p-dimensional vector of regression coefficients associated to X
- seed: random seed (defaults to 1)

Value
A vector of survival times

Author(s)
Mirko Signorelli

References

Examples

```r
# generate example data
gen <- function(n = 50)
  X = cbind(matrix(1, n, 1), matrix(rnorm(n*9, sd = 0.7), n, 9))
  beta = rnorm(10, sd = 0.7)
  times = simulate_t_weibull(n = n, lambda = 1, nu = 2, X = X, beta = beta)
  hist(times, 20)
```

**summarize_lmms**

*Step 2 of PRC-LMM (computation of the predicted random effects)*

**Description**

This function performs the second step for the estimation of the PRC-LMM model proposed in Signorelli et al. (2021).

**Usage**

```
summarize_lmms(object, n.cores = 1, verbose = TRUE)
```

**Arguments**

- `object`: a list of objects as produced by `fit_lmms`
- `n.cores`: number of cores to use to parallelize the computation of the cluster bootstrap optimism correction procedure. If `n.cores = 1` (default), no parallelization is done. Pro tip: you can use `parallel::detectCores()` to check how many cores are available on your computer.
- `verbose`: if `TRUE` (default and recommended value), information on the ongoing computations is printed in the console.

**Value**

A list containing the following objects:

- `call`: the function call
- `ranef.orig`: a matrix with the predicted random effects computed for the original data;
- `n.boots`: number of bootstrap samples;
- `boot.ids`: a list with the ids of bootstrapped subjects (when `n.boots > 0`);
- `ranef.boot.train`: a list where each element is a matrix that contains the predicted random effects for each bootstrap sample (when `n.boots > 0`);
- `ranef.boot.valid`: a list where each element is a matrix that contains the predicted random effects on the original data, based on the lmms fitted on the cluster bootstrap samples (when `n.boots > 0`).

survpred_prclmm

Compute the predicted survival probabilities obtained from the PRC models
**survpred_prclmm**

**Description**
This function computes the predictive survival probabilities for the for the PRC-LMM model proposed in Signorelli et al. (2021)

**Usage**

```r
survpred_prclmm(step1, step2, step3, times = 1, new.longdata = NULL, new.basecovs = NULL, keep.ranef = FALSE)
```

**Arguments**

- `step1`: the output of `fit_lmms` (step 1 of the estimation of PRC-LMM)
- `step2`: the output of `summarize_lmms` (step 2 of the estimation of PRC-LMM)
- `step3`: the output of `fit_prclmm` (step 3 of the estimation of PRC-LMM)
- `times`: numeric vector with the time points at which to estimate the time-dependent AUC
- `new.longdata`: longitudinal data if you want to compute predictions for new subjects on which the model was not trained. Default is NULL
- `new.basecovs`: a dataframe with baseline covariates for the new subjects for which predictions are to be computed. Only needed if baseline covariates where included in step 3 and `new.longdata` is specified. Default is NULL
- `keep.ranef`: should a data frame with the predicted random effects be included in the output? Default is FALSE

**Value**

A list containing the function call (`call`), a data frame with the predicted survival probabilities computed at the supplied time points (`predicted_survival`), and if `keep.ranef = TRUE` also the predicted random effects `predicted_ranefs`.
