Package ‘rgl’

November 21, 2021

Version 0.108.3

Title 3D Visualization Using OpenGL

Depends R (>= 3.3.0)

Suggests MASS, rmarkdown, deldir (>= 1.0-4), orientlib, lattice, misc3d, magick, plotrix (>= 3.7-3), tripack, interp, alphashape3d, tcltk, js (>= 1.2), akima, webshot2, downlit (>= 0.4.0), pkgdown, extrafont, shiny, manipulateWidget (>= 0.9.0), testthat, markdown, crosstalk

Imports graphics, grDevices, stats, utils, htmlwidgets, htmltools, knitr (>= 1.33), jsonlite (>= 0.9.20), magrittr, R6

Enhances waldo

Description Provides medium to high level functions for 3D interactive graphics, including functions modelled on base graphics (plot3d(), etc.) as well as functions for constructing representations of geometric objects (cube3d(), etc.). Output may be on screen using OpenGL, or to various standard 3D file formats including WebGL, PLY, OBJ, STL as well as 2D image formats, including PNG, Postscript, SVG, PGF.

License GPL

SystemRequirements OpenGL, GLU Library, XQuartz (on OSX), zlib (optional), libpng (>=1.2.9, optional), FreeType (optional), pandoc (>=1.14, needed for vignettes; if not present, markdown package will be used)

BugReports https://github.com/dmurdoch/rgl/issues

rgl-package

3D visualization device system

Description

3D real-time rendering system.

Details

RGL is a 3D real-time rendering system for R. Multiple windows are managed at a time. Windows may be divided into “subscenes”, where one has the current focus that receives instructions from the R command-line. The device design is oriented towards the R device metaphor. If you send scene management instructions, and there’s no device open, it will be opened automatically. Opened devices automatically get the current device focus. The focus may be changed by using `set3d()` or `useSubscene3d()`.

RGL provides medium to high level functions for 3D interactive graphics, including functions modelled on base graphics (`plot3d()`, etc.) as well as functions for constructing geometric objects (`cube3d()`, etc.). Output may be on screen using OpenGL, or to various standard 3D file formats including WebGL, PLY, OBJ, STL as well as 2D image formats, including PNG, Postscript, SVG, PGF.

The `open3d()` function attempts to open a new RGL window, using default settings specified by the user.

RGL also includes a lower level interface which is described in the `rgl.open` help topic. We recommend that you avoid mixing `rgl.*` and `*3d` calls.

See the first example below to display the ChangeLog.
.check3d

Check for an open RGL window.

Description

Mostly for internal use, this function returns the current device number if one exists, or opens a new device and returns that.

Usage

.check3d()

Value

The device number of an RGL device.

Author(s)

Duncan Murdoch

See Also

open3d

Examples

rgl.dev.list()
.check3d()
rgl.dev.list()
.check3d()
rgl.dev.list()
.check3d()
rgl.close()
abclines3d

Lines intersecting the bounding box

Description

This adds mathematical lines to a scene. Their intersection with the current bounding box will be drawn.

Usage

abclines3d(x, y = NULL, z = NULL, a, b = NULL, c = NULL, ...)

Arguments

x, y, z Coordinates of points through which each line passes.
a, b, c Coordinates of the direction vectors for the lines.
... Material properties.

Details

Draws the segment of a line that intersects the current bounding box of the scene using the parametrization \((x, y, z) + (a, b, c) \cdot s\) where \(s\) is a real number.

Any reasonable way of defining the coordinates \(x, y, z\) and \(a, b, c\) is acceptable. See the function \texttt{xyz.coords} for details.

Value

A shape ID of the object is returned invisibly.

See Also

\texttt{planes3d}, \texttt{rgl.planes} for mathematical planes.
\texttt{segments3d} draws sections of lines that do not adapt to the bounding box.

Examples

\begin{verbatim}
plot3d(rnorm(100), rnorm(100), rnorm(100))
abclines3d(0, 0, 0, a = diag(3), col = "gray")
\end{verbatim}
addNormals

*Add normal vectors to objects so they render more smoothly*

**Description**

This generic function adds normals at each of the vertices of a polyhedron by averaging the normals of each incident face. This has the effect of making the surface of the object appear smooth rather than faceted when rendered.

**Usage**

```r
addNormals(x, ...)  
## S3 method for class 'mesh3d'  
addNormals(x, angleWeighted = TRUE, ...)
```

**Arguments**

- `x`: An object to which to add normals.
- `...`: Additional parameters which will be passed to the methods.
- `angleWeighted`: See Details below.

**Details**

Currently methods are supplied for "mesh3d" and "shapelist3d" classes.

These methods work by averaging the normals on the faces incident at each vertex. By default these are weighted according to the angle in the polygon at that vertex. If `angleWeighted = FALSE`, a slightly faster but less accurate weighting by the triangle area is used.

Prior to rgl version 0.104.12 an incorrect weighting was used; it can be partially reproduced by using `angleWeighted = NA`, but not all the bugs in that scheme will be kept.

**Value**

A new object of the same class as `x`, with normals added.

**Author(s)**

Duncan Murdoch

**Examples**

```r
open3d()  
y <- subdivision3d(tetrahedron3d(col = "red"), depth = 3)  
shade3d(y) # No normals  
y <- addNormals(y)  
shade3d(translate3d(y, x = 1, y = 0, z = 0)) # With normals
```
ageControl

Set attributes of vertices based on their age

Description

This is a function to produce actions in response to a playwidget or Shiny input control. The mental model is that each of the vertices of some object has a certain birth time; a control sets the current time, so that vertices have ages depending on the control setting. Attributes of those vertices can then be changed.

Usage

ageControl(births, ages, objids = tagged3d(tags), tags, value = 0, colors = NULL, alpha = NULL, radii = NULL, vertices = NULL, normals = NULL, origins = NULL, texcoords = NULL, x = NULL, y = NULL, z = NULL, red = NULL, green = NULL, blue = NULL)

Arguments

births       Numeric birth times of vertices.
ages         Chosen ages at which the following attributes will apply.
objids       Object ids to which the changes apply.
tags         Alternate way to specify objids. Ignored if objids is given.
value        Initial value; typically overridden by input.
colors, alpha, radii, vertices, normals, origins, texcoords
             Attributes of the vertices that can be changed. There should be one entry or row for each entry in ages.

x, y, z, red, green, blue
             These one-dimensional components of vertices and colors are provided for convenience.

Details

All attributes must have the same number of entries (rows for the matrices) as the ages vector. The births vector must have the same number of entries as the number of vertices in the object.

Not all objects contain all attributes; if one is chosen that is not a property of the corresponding object, a Javascript alert() will be generated. (This restriction may be removed in the future by attempting to add the attribute when it makes sense.)

If a births entry is NA, no change will be made to that vertex.

Value

A list of class "rglControl" of cleaned up parameter values, to be used in an RGL widget.
Author(s)
Duncan Murdoch

Examples

```r
saveopts <- options(rgl.useNULL = TRUE)

theta <- seq(0, 4*pi, len=100)
xyz <- cbind(sin(theta), cos(theta), sin(theta/2))
lineid <- plot3d(xyz, type="l", alpha = 0, lwd = 5, col = "blue")["data"]

widget <- rglwidget()
playwidget(ageControl(births = theta,
  ages = c(-4*pi, -4*pi, 1-4*pi, 0, 0, 1),
  objids = lineid,
  alpha = c(0, 1, 0, 0, 1, 0)),
  start = 0, stop = 4*pi,
  step = 0.1, rate = 4)
if (interactive() || in_pkgdown_example())
  widget
options(saveopts)
```

---

**ageSetter**

*Obsolete function to set WebGL scene properties based on the age of components of objects*

Description

Many RGL shapes contain lists of vertices with various attributes (available via `rgl.attrib`). This function modifies the data for those attributes in a WebGL scene.

Usage

```r
ageSetter(births, ages,
  colors = NULL, alpha = NULL, radii = NULL,
  vertices = NULL, normals = NULL, origins = NULL,
  texcoords = NULL,
  objids, prefixes = ",", digits = 7,
  param = seq(floor(min(births)), ceiling(max(births))))
```

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>births</td>
<td>Numeric vector with one value per vertex, used to determine the “age” of the vertex when displaying it.</td>
</tr>
<tr>
<td>ages</td>
<td>A non-decreasing sequence of “ages”.</td>
</tr>
<tr>
<td>colors, alpha, radii, vertices, normals, origins, texcoords</td>
<td>Attributes of the vertices. Non-NULL attributes will be interpolated from these values. See the Details section below.</td>
</tr>
</tbody>
</table>
objids, prefixes
The object ids and scene prefixes to modify. These are recycled to the same length.
digits
How many digits to output in the generated Javascript code.
param
Default values to be used by a slider control calling the generated function.

Details
The vertex attributes are specified as follows:

colors  A vector of colors in a format suitable for input to \texttt{col2rgb}
alphas  A numeric vector of alpha values between 0 and 1.
radii   A numeric vector of sphere radii.
vertices A 3-column matrix of vertex coordinates.
normals  A 3-column matrix of vertex normals.
origins  A 2-column matrix of origins for text or sprites.
texcoords A 2-column matrix of texture coordinates.

All attributes must have the same number of entries (rows for the matrices) as the ages vector. The births vector must have the same number of entries as the number of vertices in the object.

Not all objects contain all attributes listed here; if one is chosen that is not a property of the corresponding object, a Javascript alert() will be generated.

Value
A character vector of class \texttt{c("ageSetter","propertySetter")} containing Javascript code defining a function suitable for use in \texttt{propertySlider}.

The function takes a single argument, time, and uses it to compute the “age” of vertex i as time -births[i]. Those are then used with the ages argument to linearly interpolate settings of the specified attributes. Extrapolation is constant. Repeated values in ages can be used to obtain discontinuities in the settings.

Author(s)
Duncan Murdoch

See Also
\texttt{propertySlider}; more detailed control is available in \texttt{vertexSetter}. 
all.equal.mesh3d  

Compare mesh3d objects in a meaningful way.

Description

These functions allow comparison of mesh3d objects, ignoring irrelevant differences.

compare_proxy.mesh3d can function as a compare_proxy method for the `waldo` package, by stripping out NULL components and ordering other components alphabetically by name.

all.equal.mesh3d compares mesh3d objects by using compare_proxy.mesh3d to standardize them, then using the regular all.equal function to compare them.

Usage

```r
## S3 method for class 'mesh3d'
all.equal(target, current, ...)
compare_proxy.mesh3d(x, path = "x")
```

Arguments

- `target, current`  
  Two mesh3d objects to compare.
- `x`  
  A single mesh3d object to standardize.
- `path`  
  The string to use in a `waldo` display of this object.
- `...`  
  Additional parameters to pass to all.equal.

Value

all.equal.mesh3d returns TRUE, or a character vector describing (some of) the differences.

compare_proxy.mesh3d returns a list containing two components:

- `object` a copy of `x` with relevant components in alphabetical order.
- `path` a modification of the path label for `x`

Note

`waldo` is not an installation requirement for `rgl` and `rgl` will never cause it to be loaded. The compare_proxy.mesh3d function will only be registered as a method for `waldo::compare_proxy` if you load `waldo` before `rgl`, as would normally happen during testing using `testthat`, or if you load it before calling mesh3d, as might happen if you are doing manual tests.
Description

Given starting and ending points on a sphere and the center of the sphere, draw the great circle arc between the starting and ending points. If the starting and ending points have different radii, a segment of a logarithmic spiral will join them.

Usage

\[ \text{arc3d(from, to, center, radius, n, circle = 50, base = 0, plot = TRUE, ...)} \]

Arguments

- \text{from} \hspace{1cm} \text{One or more points from which to start arcs.}
- \text{to} \hspace{1cm} \text{One or more destination points.}
- \text{center} \hspace{1cm} \text{One or more center points.}
- \text{radius} \hspace{1cm} \text{If not missing, a vector of length} \text{n} \text{giving the radii at each point between} \text{from} \text{and} \text{to}. \text{If missing, the starting and ending points will be joined by a logarithmic spiral.}
- \text{n} \hspace{1cm} \text{If not missing, how many segments to use between the first and last point. If missing, a value will be calculated based on the angle between starting and ending points as seen from the center.}
- \text{circle} \hspace{1cm} \text{How many segments would be used if the arc went completely around a circle.}
- \text{base} \hspace{1cm} \text{See Details below.}
- \text{plot} \hspace{1cm} \text{Should the arcs be plotted, or returned as a matrix?}
- \text{...} \hspace{1cm} \text{Additional parameters to pass to} \text{points3d.}

Details

If any of \text{from}, \text{to} or \text{center} is an \text{n} by 3 matrix with \text{n} > 1, multiple arcs will be drawn by recycling each of these parameters to the number of rows of the longest one.

If the vector lengths of \text{from} - \text{center} and \text{to} - \text{center} differ, then instead of a spherical arc, the function will draw a segment of a logarithmic spiral joining the two points.

By default, the arc is drawn along the shortest great circle path from \text{from} to \text{to}, but the \text{base} parameter can be used to modify this. If \text{base} = 1 is used, the longer arc will be followed. Larger positive integer values will result in \text{base} -1 loops in that direction completely around the sphere. Negative values will draw the curve in the same direction as the shortest arc, but with \text{abs(base)} full loops. It doesn’t make much sense to ask for such loops unless the radii of \text{from} and \text{to} differ, because spherical arcs would overlap. Normally the \text{base} parameter is left at its default value of 0.

When \text{base} is non-zero, the curve will be constructed in multiple pieces, between \text{from}, \text{to}, -\text{from} and -\text{to}, for as many steps as necessary. If \text{n} is specified, it will apply to each of these pieces.
Value

If `plot = TRUE`, called mainly for the side effect of drawing arcs. Invisibly returns the object ID of the collection of arcs.

If `plot = FALSE`, returns a 3 column matrix containing the points that would be drawn as the arcs.

Author(s)

Duncan Murdoch

Examples

```r
normalize <- function(v) v/sqrt(sum(v^2))
# These vectors all have the same length
from <- t(apply(matrix(rnorm(9), ncol = 3), 1, normalize))
to <- normalize(rnorm(3))
center <- c(0, 0, 0)

open3d()
spheres3d(center, radius = 1, col = "white", alpha = 0.2)
arc3d(from, to, center, col = "red")
arc3d(from, 2*to, center, col = "blue")
text3d(rbind(from, to, center, 2*to),
   text = c(paste0("from", 1:3), "to", "center", "2*to"),
   depth_mask = FALSE, depth_test = "always")
```

arrow3d

Draw an arrow

Description

Draws various types of arrows in a scene.

Usage

```r
arrow3d(p0 = c(1, 1, 1), p1 = c(0, 0, 0),
   barblen, s = 1/3, theta = pi/12,
   type = c("extrusion", "lines", "flat", "rotation"),
   n = 3, width = 1/3, thickness = 0.618 * width,
   spriteOrigin = NULL,
   plot = TRUE, ...)
```
arrow3d

Arguments

- **p0**: The base of the arrow.
- **p1**: The head of the arrow.
- **barblen**: The length of the barbs (in display coordinates). Default given by *s*.
- **s**: The length of the barbs as a fraction of line length. Ignored if **barblen** is present.
- **theta**: Opening angle of barbs.
- **type**: Type of arrow to draw. Choose one from the list of defaults. Can be abbreviated. See below.
- **n**: Number of barbs.
- **width**: Width of shaft as fraction of barb width.
- **thickness**: Thickness of shaft as fraction of barb width.
- **spriteOrigin**: If arrow is to be replicated as sprites, the origins relative to which the sprites are drawn.
- **plot**: If TRUE (the default), plot the object; otherwise return the computed data that would be used to plot it.

... Material properties passed to **polygon3d**, **shade3d** or **segments3d**.

Details

Four types of arrows can be drawn. The shapes of all of them are affected by **p0**, **p1**, **barblen**, **s**, **theta**, material properties in ..., and **spriteOrigin**. Other parameters only affect some of the types, as shown.

- "extrusion" (default) A 3-dimensional flat arrow, drawn with **shade3d**. Affected by **width**, **thickness** and **smooth**.
- "lines" Drawn with lines, similar to **arrows**, drawn with **segments3d**. Affected by **n**.
- "flat" A flat arrow, drawn with **polygon3d**. Affected by **width** and **smooth**.
- "rotation" A solid of rotation, drawn with **shade3d**. Affected by **n** and **width**.

Normally this function draws just one arrow from **p0** to **p1**, but if **spriteOrigin** is given (in any form that **xyz.coords** can handle), arrows will be drawn for each point specified, with **p0** and **p1** interpreted relative to those origins. The arrows will be drawn as 3D sprites which will maintain their orientation as the scene is rotated, so this is a good way to indicate particular locations of interest in the scene.

Value

If **plot** = TRUE (the default), this is called mainly for the side effect of drawing the arrow; invisibly returns the id(s) of the objects drawn.

If **plot** = FALSE, the data that would be used in the plot (not including material properties) is returned.

Author(s)

Design based on **heplots::arrow3d**, which contains modifications by Michael Friendly to a function posted by Barry Rowlingson to R-help on 1/10/2010. Additions by Duncan Murdoch.
as.mesh3d

Convert object to mesh object

Description

The as.mesh3d generic function converts various objects to mesh3d objects.

The default method takes a matrix of vertices as input and (optionally) merges repeated vertices, producing a mesh3d object as output. It will contain either triangles or quads or segments or points according to the type argument.

If the generic is called without any argument, it will pass all RGL ids from the current scene to the as.mesh3d.rglId method.

Usage

as.mesh3d(x, ...)  

## Default S3 method:

as.mesh3d(x, y = NULL, z = NULL,  
type = c("triangles", "quads", "segments", "points"),  
smooth = FALSE,  
tolerance = sqrt(.Machine$double.eps),  
notEqual = NULL,  
merge = TRUE,  
...,  
triangles)

Arguments

x, y, z  
For the generic, x is the object to convert. For the default method, x, y and z are coordinates. Any reasonable way of defining the coordinates is acceptable. See the function xyz.coords for details.

type  
What type of things should be in the mesh? Tries this list in order until it finds one that works.

smooth  
If TRUE, addNormals will be called on the mesh object to make it render smoothly.

tolerance  
The numerical tolerance to be used in all.equal to determine whether two vertices should be merged.
as.mesh3d

notEqual If not NULL, an n by n matrix of logical values, where n is the number of vertices as input. TRUE entries indicate that the corresponding pair of vertices should not be merged even if they appear equal.

merge Should apparently equal vertices be merged?

... Material properties to pass to tmesh3d or qmesh3d.

triangles Deprecated. If present, TRUE indicates type = "triangles" and FALSE indicates type = "quads".

Details

The motivation for this function is the following problem: I was asked whether RGL could render a surface made up of triangles or quadrilaterals to look smooth. It can do that, but needs normals at each vertex; they should be the average of the normals for each polygon sharing that vertex. Then OpenGL will interpolate the normals across the polygons and give the illusion of smoothness.

To do this, it needs to know which polygons share each vertex. If the surface is described as a list of triangles or quadrilaterals, that means identifying vertices that are in multiple polygons, and converting the representation to a "mesh3d" object (which is a matrix of vertices and a matrix of vertex numbers making up triangles or quads). Then the addNormals function will add the normals.

Sometimes two polygons will share vertices (within numerical tolerance) without the user wanting them to be considered internal to the surface, or might want one sharp edge in an otherwise smooth surface. This means I needed a way to declare that two vertices from the original list of vertices in the triangles or quads are "not equal", even when they test numerically equal. That’s what the notEqual matrix specifies.

Value

A "mesh3d" object with the same faces as in the input, but (if merge=TRUE) with vertices that test equal to within tolerance merged.

Duncan Murdoch

Examples

```r
xyz <- matrix(c(-1, -1, -1,
-1, 1, -1,
1, 1, -1,
1, -1, -1,
-1, 1, -1,
-1, 1, 1,
1, 1, 1,
1, -1, -1,
1, -1, -1,
1, 1, -1,
1, 1, 1,
1, -1, 1), byrow = TRUE, ncol = 3)
mesh <- as.mesh3d(xyz, type = "quads", col = "red")
mesh$vb
```
mesh$ib
open3d()
shade3d(mesh)

# Stop vertices 2 and 5 from being merged
notEQ <- matrix(FALSE, 12, 12)
notEQ[2, 5] <- TRUE
mesh <- as.mesh3d(xyz, type = "quads", notEqual = notEQ)
mesh$vb
mesh$ib

---

as.mesh3d.ashape3d  
_Convert alpha-shape surface of a cloud of points to RGL mesh object_

**Description**

The `alphashape3d::ashape3d` function computes the 3D $\alpha$-shape of a cloud of points. This is an approximation to the visual outline of the cloud. It may include isolated points, line segments, and triangular faces: this function converts the triangular faces to an RGL `tmesh3d` object.

**Usage**

```r
## S3 method for class 'ashape3d'
as.mesh3d(x,
          alpha = x$alpha[1],
          tri_to_keep = 2L,
          col = "gray",
          smooth = FALSE, normals = NULL,
          texcoords = NULL, ...)
```

**Arguments**

- **x**  
  An object of class "ashape3d".

- **alpha**  
  Which $\alpha$ value stored in x should be converted?

- **tri_to_keep**  
  Which triangles to keep. Expert use only: see `triang` entry in `Value` section of `ashape3d` for details.

- **col**  
  The surface colour.

- **smooth**  
  Whether to attempt to add normals to make the surface look smooth. See the Details below.

- **normals, texcoords**  
  Normals and texture coordinates at each vertex can be specified.

- **...**  
  Additional arguments to pass to use as `material3d` properties on the resulting mesh.
Details

Edelsbrunner and Mucke’s (1994) \(\alpha\)-shape algorithm is intended to compute a surface of a general cloud of points. Unlike the convex hull, the cloud may have voids, isolated points, and other oddities. This function is designed to work in the case where the surface is made up of simple polygons.

If smooth = TRUE, this method attempts to orient all of the triangles in the surface consistently and add normals at each vertex by averaging the triangle normals. However, for some point clouds, the \(\alpha\)-shape will contain sheets of polygons with a few solid polyhedra embedded. This does not allow a consistent definition of "inside" and outside. If this is detected, a warning is issued and the resulting mesh will likely contain boundaries where the assumed orientation of triangles changes, resulting in ugly dark lines through the shape. Larger values of alpha in the call to \texttt{alphashape3d::ashape3d} may help.

Methods for \texttt{plot3d} and \texttt{persp3d} are also defined: they call the \texttt{as.mesh3d} method and then plot the result.

Value

A "mesh3d" object, suitable for plotting.

Examples

```r
if (requireNamespace("alphashape3d", quietly = TRUE)) {
  set.seed(123)
  n <- 400  # 1000 gives a nicer result, but takes longer
  xyz <- rbind(cbind(runif(n), runif(n), runif(n)),
               cbind(runif(n/8, 1, 1.5),
                    runif(n/8, 0.25, 0.75),
                    runif(n/8, 0.25, 0.75)))
  ash <- suppressMessages(alphashape3d::ashape3d(xyz, alpha = 0.2))
  m <- as.mesh3d(ash, smooth = TRUE)
  open3d()
  mfrow3d(1, 2, sharedMouse = TRUE)
  plot3d(xyz, size = 1)
  plot3d(m, col = "red", alpha = 0.5)
  points3d(xyz, size = 1)
}
```
as.mesh3d.rglId

Convert object in plot to RGL mesh object

Description

This method attempts to read the attributes of objects in the rgl display and construct a mesh3d object to approximate them.

Usage

## S3 method for class 'rglId'
as.mesh3d(x, type = NA, subscene = NA, ...)

Arguments

x A vector of RGL identifiers of objects in the specified subscene.
type A vector of names of types of shapes to convert. Other shapes will be ignored.
subscene Which subscene to look in; the default NA specifies the current subscene.
... Ignored.

Details

This function attempts to construct a triangle mesh to approximate one or more objects from the current display. It can handle objects of types from c("points","lines","linestrip","triangles","quads","planes","surfaces"). Since this method only produces meshes containing points, segments and triangles, they won’t necessarily be an exact match to the original object.

If the generic as.mesh3d is called with no x argument, this method will be called with x set to the ids in the current scene.

Value

A mesh object.

as.triangles3d.rglId for extracting the triangles, clipMesh3d to apply complex clipping to a mesh object.
Examples

# volcano example taken from "persp"
#
data(volcano)

z <- 2 * volcano       # Exaggerate the relief
x <- 10 * (1:nrow(z))   # 10 meter spacing (S to N)
y <- 10 * (1:ncol(z))   # 10 meter spacing (E to W)

zlim <- range(y)

colorlut <- terrain.colors(zlen) # height color lookup table

col <- colorlut[ z - zlim[1] + 1 ] # assign colors to heights for each point

open3d(useNULL = TRUE)
surface3d(x, y, z, color = col)
m <- as.mesh3d()
close3d()

open3d()
shade3d(m)

as.rglscene(x, ...)  
Convert an object to an rglscene object.

Description

This is a placeholder generic function, to allow other packages to create "rglscene" objects compatible with the objects produced by scene3d.

No methods are currently defined in rgl.

Usage

as.rglscene(x, ...)

Arguments

x Object to convert.

... Other parameters to pass to methods.
as.tmesh3d  

Convert object to a triangular mesh

Description

Converts the quads in a mesh version of an object to triangles by splitting them up. Optionally drops any point or segment components.

Usage

as.tmesh3d(x, ...)  

Arguments

- `x` An object from which to create a triangular mesh object.
- `drop` If TRUE, drop any point or segment components.
- `...` Ignored in the mesh3d method, passed to as.mesh3d in the default method.

Details

The default method simply calls as.mesh3d(x, ...) and passes the result to the "mesh3d" method.

Value

A "mesh3d" object containing no quads. If drop = TRUE, it will only contain triangles.

Note

Older versions of rgl had a "tmesh3d" class for meshes of triangles. That class is no longer used: as.tmesh3d and tmesh3d both produce "mesh3d" objects.

Author(s)

Duncan Murdoch

See Also

as.triangles3d to get just the coordinates.

Examples

```r
x <- cuboctahedron3d()
x  
# has quads and triangles
as.tmesh3d(x)  
# has only triangles
```
as.triangles3d

Convert an object to triangles

Description

This generic and its methods extract or creates a matrix of coordinates of triangles from an object, suitable for passing to triangles3d.

Usage

as.triangles3d(obj, ...)
## S3 method for class 'rglId'
as.triangles3d(obj,
    attribute = c("vertices", "normals", "texcoords", "colors"),
    subscene = NA,
    ...)

Arguments

obj The object to convert.
attribute Which attribute of an RGL object to extract?
subscene Which subscene is this object in?
... Additional arguments used by the methods.

Details

The method for "rglId" objects can extract several different attributes, organizing them as it would organize the vertices for the triangles.

Value

An n x 3 matrix containing the vertices of triangles making up the object. Each successive 3 rows of the matrix corresponds to a triangle.

If the attribute doesn’t exist, NULL will be returned.

Author(s)

Duncan Murdoch

See Also

as.mesh3d to also capture material properties.
Examples

```r
open3d()
x <- surface3d(x = 1:10, y = 1:10, z = rnorm(100), col = "red")
tri <- as.triangles3d(x)
open3d()
triangles3d(tri, col = "blue")
```

Description

This function sets the apparent ratios of the x, y, and z axes of the current bounding box.

Usage

```r
aspect3d(x, y = NULL, z = NULL)
```

Arguments

- `x` The ratio for the x axis, or all three ratios, or "iso"
- `y` The ratio for the y axis
- `z` The ratio for the z axis

Details

If the ratios are all 1, the bounding box will be displayed as a cube approximately filling the display. Values may be set larger or smaller as desired. Aspect "iso" signifies that the coordinates should all be displayed at the same scale, i.e. the bounding box should not be rescaled. (This corresponds to the default display before `aspect3d` has been called.) Partial matches to "iso" are allowed. `aspect3d` works by modifying `par3d("scale")`.

Value

The previous value of the scale is returned invisibly.

Author(s)

Duncan Murdoch

See Also

`plot3d`, `par3d`
Examples

```r
x <- rnorm(100)
y <- rnorm(100)*2
z <- rnorm(100)*3

open3d()
plot3d(x, y, z)
aspect3d(1, 1, 0.5)
highlevel()  # To trigger display
open3d()
plot3d(x, y, z)
aspect3d("iso")
highlevel()
```

asRow

Convenience functions for RGL HTML layouts

Description

The asRow function arranges objects in a row in the display; the getWidgetId function extracts the HTML element ID from an HTML widget.

Usage

```r
asRow(..., last = NA, height = NULL, colsize = 1)
getWidgetId(widget)
```

Arguments

- `...` Either a single "combineWidgets" object produced by asRow or a %>% pipe of RGL objects, or several objects intended for rearrangement.
- `last` If not NA, the number of objects from ... that are to be arranged in a row. Earlier ones will remain in a column.
- `height` An optional height for the resulting row. This is normally specified in pixels, but will be rescaled as necessary to fit the display.
- `colsize` A vector of relative widths for the columns in the row.
- `widget` A single HTML widget from which to extract the HTML element ID.

Details

Using asRow requires that the manipulateWidget package is installed.

asRow produces a "combineWidgets" object which is a single column whose last element is another "combineWidgets" object which is a single row.

If n objects are given as input and last is given a value less than n, the first n - last objects will be displayed in a column above the row containing the last objects.
Value

asRow returns a single "combineWidgets" object suitable for display or nesting within a more complicated display.

getWidgetId returns a character string containing the HTML element ID of the widget.

pipe for the %>% operator.

Examples

if (requireNamespace("manipulateWidget", quietly = TRUE) &&
 require("crosstalk", quietly = TRUE)) {
  sd <- SharedData$new(mtcars)
  ids <- plot3d(sd$origData(), col = mtcars$cyl, type = "s")
  # Copy the key and group from existing shared data
  rglsd <- rglShared(ids["data"], key = sd$key(), group = sd$groupName())
  w <- rglwidget(shared = rglsd) %>%
    asRow("Mouse mode: ", rglMouse(getWidgetId(.)),
          "Subset: ", filter_checkbox("cylinderselector",
          "Cylinders", sd, ~ cyl, inline = TRUE),
          last = 4, colsize = c(1,2,1,2), height = 60)
  if (interactive() || in_pkgdown_example())
    w
}

axes3d

Draw boxes, axes and other text outside the data

Description

These functions draw axes, boxes and text outside the range of the data. axes3d, box3d and title3d
are the higher level functions; normally the others need not be called directly by users.

Usage

axes3d(edges = "bbox", labels = TRUE, tick = TRUE, nticks = 5,
box = FALSE, expand = 1.03, ...)  
box3d(...)  
title3d(main = NULL, sub = NULL, xlab = NULL, ylab = NULL,
zlab = NULL, line = NA, level = NA, floating = NULL, ...)  
axis3d(edge, at = NULL, labels = TRUE, tick = TRUE, line = 0,
pos = NULL, nticks = 5, ...)  
mtext3d(text, edge, at = NULL, line = 0, level = 0,
        floating = FALSE, pos = NA, ...)

axes3d

Draw boxes, axes and other text outside the data

Description

These functions draw axes, boxes and text outside the range of the data. axes3d, box3d and title3d
are the higher level functions; normally the others need not be called directly by users.

Usage

axes3d(edges = "bbox", labels = TRUE, tick = TRUE, nticks = 5,
box = FALSE, expand = 1.03, ...)  
box3d(...)  
title3d(main = NULL, sub = NULL, xlab = NULL, ylab = NULL,
zlab = NULL, line = NA, level = NA, floating = NULL, ...)  
axis3d(edge, at = NULL, labels = TRUE, tick = TRUE, line = 0,
pos = NULL, nticks = 5, ...)  
mtext3d(text, edge, at = NULL, line = 0, level = 0,
        floating = FALSE, pos = NA, ...)

axes3d

Draw boxes, axes and other text outside the data

Description

These functions draw axes, boxes and text outside the range of the data. axes3d, box3d and title3d
are the higher level functions; normally the others need not be called directly by users.

Usage

axes3d(edges = "bbox", labels = TRUE, tick = TRUE, nticks = 5,
box = FALSE, expand = 1.03, ...)  
box3d(...)  
title3d(main = NULL, sub = NULL, xlab = NULL, ylab = NULL,
zlab = NULL, line = NA, level = NA, floating = NULL, ...)  
axis3d(edge, at = NULL, labels = TRUE, tick = TRUE, line = 0,
pos = NULL, nticks = 5, ...)  
mtext3d(text, edge, at = NULL, line = 0, level = 0,
        floating = FALSE, pos = NA, ...)
**axes3d** 27

**Arguments**

- **edges**
  a code to describe which edge(s) of the box to use; see Details below

- **labels**
  whether to label the axes, or (for `axis3d`) the labels to use

- **tick**
  whether to use tick marks

- **nticks**
  suggested number of ticks

- **box**
  draw the full box if "bbox" axes are used

- **expand**
  how much to expand the box around the data

- **main**
  the main title for the plot

- **sub**
  the subtitle for the plot

- **xlab, ylab, zlab**
  the axis labels for the plot

- **line, level**
  the "line" of the plot margin to draw the label on, and "level" above or below it

- **floating**
  which mode of axis labels? One of TRUE, FALSE or NA. (NULL may also be used in `title3d` calls). See Details for how these are handled.

- **edge, pos**
  the position at which to draw the axis or text

- **text**
  the text to draw

- **at**
  the value of a coordinate at which to draw the axis or labels.

- **...**
  additional parameters which are passed to bbox3d or material3d

**Details**

The rectangular prism holding the 3D plot has 12 edges. They are identified using 3 character strings. The first character ('x', 'y', or 'z') selects the direction of the axis. The next two characters are each '-' or '+', selecting the lower or upper end of one of the other coordinates. If only one or two characters are given, the remaining characters normally default to '-' (but with mtext3d(...,floating = TRUE) the default is '+'; see below). For example `edge = 'x+'` draws an x-axis at the high level of y and the low level of z.

By default, axes3d uses the bbox3d function to draw the axes. The labels will move so that they do not obscure the data. Alternatively, a vector of arguments as described above may be used, in which case fixed axes are drawn using axis3d.

As of **rgl** version 0.106.21, axis drawing has changed significantly. Text drawn in the margins will adapt to the margins (see bbox3d). The edge and floating parameters will be recorded in the margin and floating material properties for the object.

If `floating = FALSE`, they will be drawn on the specified edge.

If `floating = TRUE`, they will move as the axis labels move when the scene is rotated. The signs on the edge specification are interpreted as agreeing with the axis ticks '+' or disagreeing '-' . For example, "x++" will draw text on the x axis in the same edge as the ticks, while "x--" will draw on the opposite edge.

The final possible value for floating in mtext3d is NA, which reproduces legacy **rgl** behaviour. In this case the labels are not tied to the bounding box, so they should be drawn last, or they could appear inside the box, overlapping the data.
In `title3d` `floating = NULL` (the default) indicates the main title and subtitle will be fixed while the axis labels will be floating. The default locations for title and subtitle are `line = 2` and `level = 2` on edges "x++" and "x--" respectively. The axis labels float at `line = 4` and `level = 1` on the same edge as the ticks.

The `at` parameter in `axis3d` is the location of the ticks, defaulting to pretty locations. In `mtext3d` the `at` parameter is the location on the specified axis at which to draw the text, defaulting to the middle of the bounding box.

The `line` parameter is the line counting out from the box in the same direction as the axis ticks, and `level` is the line out in the orthogonal direction. The ticks run from `line = 0` to `line = 1`, and the tick labels are drawn at `line = 2`. Both are drawn at level 0.

The `pos` parameter is only supported in legacy mode. If it is a numeric vector of length 3, `edge` determines the direction of the axis and the tick marks, and the values of the other two coordinates in `pos` determine the position. The `level` parameter is ignored in legacy mode.

For `mtext3d` in `floating = TRUE` or `floating = FALSE` mode, there are 3 special values for the `at` parameter: it may be `-Inf`, `NA` or `+Inf`, referring to the bottom, middle or top of the given axis respectively.

**Value**

These functions are called for their side effects. They return the object IDs of objects added to the scene.

**Note**

`mtext3d` is a wrapper for `text3d` that sets the margin and floating material properties. In fact, these properties can be set for many kinds of objects (most kinds where it would make sense), with the effect that the object will be drawn in the margin, with x coordinate corresponding to `at`, y corresponding to `line`, and z corresponding to `level`.

**Author(s)**

Duncan Murdoch

**See Also**

Classic graphics functions `axis`, `box`, `title`, `mtext`, and RGL function `bbox3d`.

**Examples**

```r
open3d()
points3d(rnorm(10), rnorm(10), rnorm(10))

# First add standard axes
axes3d()

# and one in the middle (the NA will be ignored, a number would
# do as well)
axis3d('x', pos = c(NA, 0, 0))
```
# add titles
title3d('main', 'sub', 'xlab', 'ylab', 'zlab')

rgl.bringtotop()

open3d()
points3d(rnorm(10), rnorm(10), rnorm(10))

# Use fixed axes
axes3d(c('x', 'y', 'z'))

# Put 4 x-axes on the plot
axes3d(c('x--', 'x+-', 'x+-', 'x++'))

axis3d('x', pos = c(NA, 0, 0))
title3d('main', 'sub', 'xlab', 'ylab', 'zlab')

---

**bg3d**

*Set up background*

**Description**

Set up the background of the scene.

**Usage**

```r
bg3d(...) 
rgl.bg( sphere = FALSE, fogtype = "none", color = c("black", "white"), back = "lines", fogScale = 1, ...)
```

**Arguments**

- **fogtype**  
  fog type:
  "none" no fog
  "linear" linear fog function
  "exp" exponential fog function
  "exp2" squared exponential fog function
  Fog only applies to objects with *material3d* property fog set to TRUE.

- **sphere**  
  logical, if true, an environmental sphere geometry is used for the background decoration.

- **color**  
  Primary color is used for background clearing and as fog color. Secondary color is used for background sphere geometry. See *material3d* for details.

- **back**  
  Specifies the fill style of the sphere geometry. See *material3d* for details.

- **fogScale**  
  Scaling for fog. See Details.

- **...**  
  Material properties. See *material3d* for details.
Details

If `sphere` is set to `TRUE`, an environmental sphere enclosing the whole scene is drawn.
If not, but the material properties include a bitmap as a texture, the bitmap is drawn in the background of the scene. (The bitmap colors modify the general color setting.)
If neither a sphere nor a bitmap background is drawn, the background is filled with a solid color.

The `fogScale` parameter should be a positive value to change the density of the fog in the plot. For `fogtype = "linear"` it multiplies the density of the fog; for the exponential fog types it multiplies the density parameter used in the display.

See the 'OpenGL 2.1 reference' for the formulas used in the fog calculations within R (though the "exp2" formula appears to be wrong, at least on my system). In WebGL displays, the following rules are used. They appear to match the rules used in R on my system.

- For "linear" fog, the near clipping plane is taken as $c = 0$, and the far clipping plane is taken as $c = 1$. The amount of fog is $s \times c$ clamped to a 0 to 1 range, where $s = \text{fogScale}$.
- For "exp" and "exp2" fog, the observer location is negative at a distance depending on the field of view. The formula for the distance is $$c = \frac{[1 - \sin(\theta)]}{[1 + \sin(\theta)]}$$ where $\theta = \text{FOV}/2$. We calculate $$c' = d(1 - c) + c$$ so $c'$ runs from 0 at the observer to 1 at the far clipping plane.
- For "exp" fog, the amount of fog is $1 - \exp(-s \times c')$.
- For "exp2" fog, the amount of fog is $1 - \exp[-(s \times c')^2]$.

See Also

`material3d, bgplot3d` to add a 2D plot as background.

Examples

```r
open3d()

# a simple white background
bg3d("white")

# the holo-globe (inspired by star trek):
bg3d(sphere = TRUE, color = c("black", "green"), lit = FALSE, back = "lines")

# an environmental sphere with a nice texture.
bg3d(sphere = TRUE, texture = system.file("textures/sunsleep.png", package = "rgl"),
     back = "filled")

# The same texture as a fixed background
```
open3d()
bg3d(texture = system.file("textures/sunsleep.png", package = "rgl"), col = "white")

---

### bgplot3d

*Use base graphics for RGL background*

#### Description

Add a 2D plot or a legend in the background of an RGL window.

#### Usage

```r
gpplot3d(expression, bg.color = get3dDefaults("bg", "color"),
magnify = 1, ...)
legend3d(...)
```

#### Arguments

- `expression`: Any plotting commands to produce a plot.
- `bg.color`: The color to use for the background.
- `magnify`: Multiplicative factor to apply to size of window when producing background plot.
- `...`: For `legend3d`, arguments to pass to `bgplot3d` or `legend`; for `bgplot3d`, arguments to pass to `bg3d`.

#### Details

The `bgplot3d` function opens a `png` device and executes `expression`, producing a plot there. This plot is then used as a bitmap background for the current RGL subscene.

The `legend3d` function draws a standard 2D legend to the background of the current subscene by calling `bgplot3d` to open a device, and setting up a plot region there to fill the whole display.

#### Value

The `bgplot3d` function invisibly returns the ID of the background object that was created, with attribute "value" holding the value returned when the expression was evaluated.

The `legend3d` function does similarly. The "value" attribute is the result of the call to `legend`. The scaling of the coordinates runs from 0 to 1 in X and Y.

#### Note

Because the background plots are drawn as bitmaps, they do not resize very gracefully. It’s best to size your window first, then draw the background at that size.

# Needs to be a bigger window than the default
par3d(windowRect = c(100, 100, 612, 612))
parent <- currentSubscene3d()
mfrow3d(2, 2)
plot3d(x, y, z)
next3d(reuse = FALSE)
bgplot3d(plot(y, z))
next3d(reuse = FALSE)
bgplot3d(plot(x, z))
next3d(reuse = FALSE)
legend3d("center", c("2D Points", "3D Points"), pch = c(1, 16))
useSubscene3d(parent)

---

Buffer

R6 Class for binary buffers in glTF files.

Description
These files typically have one buffer holding all the binary data for a scene.

Methods

Public methods:
- Buffer$new()
- Buffer$load()
- Buffer$saveOpenBuffer()
- Buffer$getBuffer()
- Buffer$setBuffer()
- Buffer$openBuffer()
- Buffer$writeBuffer()
- Buffer$closeBuffer()
- Buffer$closeBuffers()
- Buffer$getBufferview()
- `Buffer$addBufferView()`
- `Buffer$openBufferView()`
- `Buffer$setBufferView()`
- `Buffer$getAccessor()`
- `Buffer$setAccessor()`
- `Buffer$readAccessor()`
- `Buffer$addAccessor()`
- `Buffer$dataURI()`
- `Buffer$as.list()`
- `Buffer$clone()`

**Method** `new()`:

*Usage:*

```
Buffer$new(json = NULL, binfile = NULL)
```

*Arguments:*

- `json` list read from glTF file.
- `binfile` optional External binary filename, or raw vector

**Method** `load()`: Load from file.

*Usage:*

```
Buffer$load(uri, buf = 0)
```

*Arguments:*

- `uri` Which file to load.
- `buf` Which buffer number to load.

**Method** `saveOpenBuffer()`: Write open buffer to connection.

*Usage:*

```
Buffer$saveOpenBuffer(con, buf = 0)
```

*Arguments:*

- `con` Output connection.
- `buf` Buffer number.

**Method** `getBuffer()`: Get buffer object.

*Usage:*

```
Buffer$getBuffer(buf, default = list(byteLength = 0))
```

*Arguments:*

- `buf` Buffer number.
- `default` Default buffer object if ‘buf’ not found.

*Returns:* A list containing components described here: [https://www.khronos.org/registry/glTF/specs/2.0/glTF-2.0.html#reference-buffer](https://www.khronos.org/registry/glTF/specs/2.0/glTF-2.0.html#reference-buffer).

**Method** `setBuffer()`: Set buffer object.

*Usage:*

```
Buffer$setBuffer(buf, buffer)

*Arguments:*
- buf  Buffer number.
- buffer New value to insert.

**Method** openBuffer(): Open a connection for the data in a buffer.

*Usage:*
Buffer$openBuffer(buf)

*Arguments:*
- buf  Buffer number.

*Returns:* An open binary connection.

**Method** writeBuffer(): Write data to buffer.

*Usage:*
Buffer$writeBuffer(values, type, size, buf = 0)

*Arguments:*
- values Values to write.
- type Type to write.
- size Byte size of each value.
- buf Which buffer to write to.

*Returns:* Byte offset of start of bytes written.

**Method** closeBuffer(): Close the connection in a buffer.
If there was a connection open, this will save the contents in the raw vector ‘bytes’ within the buffer object.

*Usage:*
Buffer$closeBuffer(buf)

*Arguments:*
- buf  The buffer number.

**Method** closeBuffers(): Close any open buffers.
Call this after working with a GLTF file to avoid warnings from R about closing unused connections.

*Usage:*
Buffer$closeBuffers()

**Method** getBufferview(): Get bufferView object.

*Usage:*
Buffer$getBufferview(bufv)

*Arguments:*
- bufv  bufferView number.

*Returns:* A list containing components described here: https://www.khronos.org/registry/gltf/specs/2.0/gltf-2.0.html#reference-bufferview.
**Method** addBufferView(): Add a new buffer view.

*Usage:*
Buffer$addBufferView(values, type, size, target = NULL, buf = 0)

*Arguments:*
- values: Values to put in the view.
- type: Type of values.
- size: Size of values in bytes.
- target: Optional target use for values.
- buf: Which buffer to write to.

*Returns:* New bufferView number.

**Method** openBufferview(): Open a connection to a buffer view.

*Usage:*
Buffer$openBufferview(bufv)

*Arguments:*
- bufv: Which bufferView.

*Returns:* A connection.

**Method** setBufferview(): Set bufferView object.

*Usage:*
Buffer$setBufferview(bufv, bufferView)

*Arguments:*
- bufv: bufferView number.
- bufferView: New value to insert.

**Method** getAccessor(): Get accessor object

*Usage:*
Buffer$getAccessor(acc)

*Arguments:*
- acc: Accessor number

*Returns:* A list containing components described here: [https://www.khronos.org/registry/glTF/specs/2.0/glTF-2.0.html#reference-accessor](https://www.khronos.org/registry/glTF/specs/2.0/glTF-2.0.html#reference-accessor)

**Method** setAccessor(): Set accessor object.

*Usage:*
Buffer$setAccessor(acc, accessor)

*Arguments:*
- acc: Accessor number.
- accessor: New value to insert.

**Method** readAccessor(): Read data given by accessor object.

*Usage:*
Buffer$readAccessor(acc)

*Arguments:*
acc Accessor number.

*Returns: A vector or array as specified in the accessor.*

**Method addAccessor():** Write values to accessor, not including 'min' and 'max'.

*Usage:*
Buffer$addAccessor(values, target = NULL, useDouble = FALSE)

*Arguments:*
values Values to write.
target Optional target use for values.
useDouble Whether to write doubles or singles.
glTF Whether this is for glTF use.

*Returns: New accessor number*

**Method dataURI():** Convert buffer to data URI.

*Usage:*
Buffer$dataURI(buf = 0)

*Arguments:*
buf Buffer to convert.

*Returns: String containing data URI.*

**Method as.list():** Convert to list.

*Usage:*
Buffer$as.list()

*Returns: List suitable for writing using JSON.*

**Method clone():** The objects of this class are cloneable with this method.

*Usage:*
Buffer$clone(deep = FALSE)

*Arguments:*
deep Whether to make a deep clone.
checkDeldir

Check for a compatible version of deldir

Description
Version 1.0-2 of deldir is not compatible with rgl. This allows code to avoid trying to call it.

Usage
checkDeldir(error = FALSE)

Arguments
error If TRUE, stop with an error.

Value
Returns TRUE if deldir is available in a compatible version.

Examples
checkDeldir()

clipMesh3d
Clip mesh or RGL object to general region

Description
Modifies a mesh3d object so that values of a function are bounded.

Usage
clipMesh3d(mesh, fn, bound = 0, greater = TRUE, minVertices = 0, plot = FALSE, keepValues = FALSE)
clipObj3d(ids = tagged3d(tags), fn, bound = 0, greater = TRUE, minVertices = 0, replace = TRUE, tags)

Arguments
mesh A mesh3d object.
fn A function used to determine clipping, or a vector of values from such a function, with one value per vertex.
bound The value(s) of fn on the clipping boundary.
greater Logical; whether to keep fn >= bound or not.
minVertices  See Details below.
plot         Logical; whether or not to plot the mesh.
keepValues   Logical; whether to save the function values at each vertex when plot = FALSE.
ids          The RGL id value(s) of objects to clip.
tags         Alternate way to specify ids. Ignored if ids is given.
replace      Should the ids objects be deleted after the clipped ones are drawn?

Details

These functions transform a mesh3d object or other RGL objects by removing parts where fn violates the bound.

For clipMesh3d the fn argument can be any of the following:
  • a character vector naming a function (with special names "x", "y", and "z" corresponding to functions returning those coordinates)
  • a function
  • a numeric vector with one value per vertex
  • NULL, indicating that the numeric values are saved in mesh$values

For clipObj3d any of the above except NULL may be used.

If fn is a numeric vector, with one value per vertex, those values will be used in the test. If it is a function with formal arguments x, y and z, it will receive the coordinates of vertices in those arguments, otherwise it will receive the coordinates in a single n x 3 matrix. The function should be vectorized and return one value per vertex, to check against the bound.

These operations are performed on the mesh:
  First, all quads are converted to triangles.
  Next, each vertex is checked against the condition.

Modifications to triangles depend on how many of the vertices satisfy the condition (fn >= bound or fn <= bound, depending on greater) for inclusion.
  • If no vertices in a triangle satisfy the condition, the triangle is omitted.
  • If one vertex satisfies the condition, the other two vertices in that triangle are shrunk towards it by assuming fn is locally linear.
  • If two vertices satisfy the condition, the third vertex is shrunk along each edge towards each other vertex, forming a quadrilateral made of two new triangles.
  • If all vertices satisfy the condition, they are included with no modifications.

Modifications to line segments are similar: the segment will be shortened if it crosses the boundary, or omitted if it is entirely out of bounds. Points, spheres, text and sprites will just be kept or rejected.

The minVertices argument is used to improve the approximation to the boundary when fn is a non-linear function. In that case, the interpolation described above can be inaccurate. If minVertices is set to a positive number (e.g. 10000), then each object is modified by subdivision to have at least that number of vertices, so that pieces are smaller and the linear interpolation is more accurate. In the clipObj3d function, minVertices can be a vector, with entries corresponding to each of the entries in ids.
clipMesh3d

Value

If plot = FALSE, clipMesh3d returns a new mesh3d object in which all vertices (approximately) satisfy the clipping condition. Note that the order of vertices will likely differ from the original order, and new vertices will be added near the boundary (and if minVertices > 0, in the interior). If in addition keepValues = TRUE, a component named "values" will be added to the mesh containing the values for each vertex.

If plot = TRUE, the result will be plotted with shade3d and its result returned.

clipObj3d is called for the side effect of modifying the scene. It returns a list of new RGL id values corresponding to the ids passed as arguments.

See https://stackoverflow.com/q/56242470/2554330 for a motivating example.

See Also

See contourLines3d and filledContour3d for ways to display function values without clipping.

Examples

# Show the problem that minVertices solves:

cube <- cube3d(col = "red")

# This function only has one argument, so it will be passed x, y and z in columns of a matrix
vecnorm <- function(vals) apply(vals, 1, function(row) sqrt(sum(row^2)))

open3d()
mfrow3d(2, 2, sharedMouse = TRUE)
id1 <- shade3d(cube)
# All vertices have norm sqrt(3), so this clips nothing:
clipObj3d(id1, fn = vecnorm, bound = sqrt(2))
next3d()
id2 <- wire3d(cube, lit = FALSE)
clipObj3d(id2, fn = vecnorm, bound = sqrt(2))

# This subdivides the cube, and does proper clipping:
next3d()
id3 <- shade3d(cube)
clipObj3d(id3, fn = vecnorm, bound = sqrt(2), minVertices = 200)
next3d()
id4 <- wire3d(cube, lit = FALSE)
clipObj3d(id4, fn = vecnorm, bound = sqrt(2), minVertices = 200)
clipplaneControl

Sets attributes of a clipping plane

Description

This is a function to produce actions in a web display. A playwidget or Shiny input control (e.g. a sliderInput control) sets a value which controls attributes of one or more clipping planes.

Usage

clipplaneControl(a = NULL, b = NULL, c = NULL, d = NULL,
               plane = 1, clipplaneids = tagged3d(tag), tag, ...)

Arguments

a, b, c, d      Parameter values for the clipping planes.
plane          Which plane in the clipplane object?
clipplaneids   The id of the clipplane object.
tag           Select clipplane with matching tag. Ignored if clipplaneid is specified.
...             Other parameters passed to propertyControl.

Value

A list of class "rglControl" of cleaned up parameter values, to be used in an RGL widget.

Author(s)

Duncan Murdoch

Examples

open3d()
saveopts <- options(rgl.useNULL = TRUE)
xyz <- matrix(rnorm(300), ncol = 3)
id <- plot3d(xyz, type="s", col = "blue", zlim = c(-3,3))[,"clipplanes"]
dvals <- c(3, -3)
widget <- rglwidget()
  playwidget(clipplaneControl(d = dvals, clipplaneids = id),
              start = 0, stop = 1, step = 0.01,
              rate = 0.5)
if (interactive() || in_pkgdown_example())
  widget
options(saveopts)
contourLines3d

**Draw contours on a surface**

**Description**

contourLines3d draws contour lines on a surface; filledContour3d draws filled contours on it.

**Usage**

```r
contourLines3d(obj, ...)  
## S3 method for class 'rglId'
contourLines3d(obj, ...)  
## S3 method for class 'mesh3d'
contourLines3d(obj, fn = "z",  
nlevels = 10,  
levels = NULL,  
minVertices = 0,  
plot = TRUE, ... )

filledContour3d(obj, ...)  
## S3 method for class 'rglId'
filledContour3d(obj, plot = TRUE, replace = plot, ...)  
## S3 method for class 'mesh3d'
filledContour3d(obj, fn = "z",  
nlevels = 20,  
levels = pretty(range(values), nlevels),  
color.palette = function(n) hcl.colors(n, "YlOrRd", rev = TRUE),  
col = color.palette(length(levels) - 1),  
minVertices = 0,  
plot = TRUE,  
keepValues = FALSE, ... )
```

**Arguments**

- `obj` The object(s) on which to draw contour lines.
- `fn` The function(s) to be contoured. See Details.
- `nlevels` Suggested number of contour levels if `levels` is not given.
- `levels` Specified contour values.
- `minVertices` See Details below.
- `plot` Whether to draw the lines or return them in a dataframe.
- `...` For the "mesh3d" methods, additional parameters to pass to `segments3d` when drawing the contour lines or to `shade3d` when drawing the filled contours. For the "rglId" methods, additional parameters to pass to the "mesh3d" methods.
- `replace` Whether to delete the objects that are being contoured.
- `color.palette` a color palette function to assign colors in the plot
- `col` the actual colors to use in the plot.
- `keepValues` whether to save the function values at each vertex when `plot = FALSE`
Details

For `contourLines3d`, the `fn` argument can be any of the following:

- a character vector naming one or more functions
- a function
- a numeric vector with one value per vertex
- `NULL`, indicating that the numeric values are saved in `obj$values`
- a list containing any of the above.

For `filledContour3d`, only one function can be specified.

The special names "x", "y", "z" may be used in `fn` to specify functions returning one of those coordinates. (If you have existing functions `x()`, `y()` or `z()` they will be masked by this choice; specify such functions by value rather than name, e.g. `fn = x` instead of `fn = "x"`.)

Functions in `fn` with formal arguments `x`, `y` and `z` will receive the coordinates of vertices in those arguments, otherwise they will receive the coordinates in a single n x 3 matrix. They should be vectorized and return one value per vertex.

Each of the functions will be evaluated at each vertex of the surface specified by `obj`, and contours will be drawn assuming the function is linear between vertices. If contours of a nonlinear function are needed, you may want to increase `minVertices` as described below.

If `levels` is not specified, values will be set separately for each entry in `fn`, using `pretty(range(values, na.rm = TRUE), nlevels)` where `values` are the values on the vertices.

The `minVertices` argument is used to improve the approximation to the contour when the function is non-linear. In that case, the interpolation between vertices can be inaccurate. If `minVertices` is set to a positive number (e.g. 10000), then the mesh is modified by subdivision to have at least that number of vertices, so that pieces are smaller and the linear interpolation is more accurate.

Value

For both `contourLines3d` and `filledContour3d` the "rglId" method converts the given id values to a mesh, and calls the "mesh3d" method.

The "mesh3d" method returns an object of class "rglId" corresponding to what was drawn if `plot` is TRUE.

If `plot` is FALSE, `contourLines3d` returns a dataframe containing columns c("x", "y", "z", "fn", "level") giving the coordinates of the endpoints of each line segment, the name (or index) of the function for this contour, and the level of the contour.

If `plot` is FALSE, `filledContour3d` returns a "mesh3d" object holding the result. If `keepValues` is TRUE, the mesh will contain the values corresponding to each vertex (with linear approximations at the boundaries).

Note

To draw contours on a surface, the surface should be drawn with material property `polygon_offset = 1` (or perhaps some larger positive value) so that the lines of the contour are not obscured by the surface.

In R versions prior to 3.6.0, the default `color.palette` is `grDevices::cm.colors`.

See Also

The misc3d package contains the function contour3d to draw contour surfaces in space instead of contour lines on surfaces.

Examples

# Add contourlines in "z" to a persp plot

z <- 2 * volcano # Exaggerate the relief
x <- 10 * (1:nrow(z)) # 10 meter spacing (S to N)
y <- 10 * (1:ncol(z)) # 10 meter spacing (E to W)

open3d()

id <- persp3d(x, y, z, aspect = "iso",
axes = FALSE, box = FALSE, polygon_offset = 1)
contourLines3d(id) # "z" is the default function
filledContour3d(id, polygon_offset = 1, nlevels = 10, replace = TRUE)

# Draw longitude and latitude lines on a globe

lat <- matrix(seq(90, -90, len = 50)*pi/180, 50, 50, byrow = TRUE)
long <- matrix(seq(-180, 180, len = 50)*pi/180, 50, 50)

r <- 6378.1 # radius of Earth in km
x <- r*cos(lat)*cos(long)
y <- r*cos(lat)*sin(long)
z <- r*sin(lat)

open3d()

ids <- persp3d(x, y, z, col = "white",
texture = system.file("textures/worldsmall.png", package = "rgl"),
specular = "black", axes = FALSE, box = FALSE, xlab = "", ylab = "", zlab = "",
normal_x = x, normal_y = y, normal_z = z, polygon_offset = 1)

contourLines3d(ids, list(latitude = function(x, y, z) asin(z/sqrt(x^2+y^2+z^2))*180/pi,
longitude = function(x, y, z) atan2(y, x)*180/pi))

cube3d

Sample 3D mesh objects

Description

A collection of sample mesh objects.
Usage

cube3d(trans = identityMatrix(), ...)  
tetrahedron3d(trans = identityMatrix(), ...)  
octahedron3d(trans = identityMatrix(), ...)  
icosahedron3d(trans = identityMatrix(), ...)  
dodecahedron3d(trans = identityMatrix(), ...)  
cuboctahedron3d(trans = identityMatrix(), ...)  

oh3d(trans = identityMatrix(), ...)    # an 'o' object

Arguments

trans  transformation to apply to objects
...
additional parameters to pass to mesh3d

Details

These sample objects optionally take a 4x4 matrix transformation trans as an argument. This transformation is applied to all vertices of the default shape. The default is an identity transformation.

Value

Objects of class c("mesh3d","shape3d").

See Also

mesh3d

Examples

# render all of the Platonic solids
open3d()
shade3d( translate3d( tetrahedron3d(col = "red"), 0, 0, 0) )
shade3d( translate3d( cube3d(col = "green"), 3, 0, 0) )
shade3d( translate3d( octahedron3d(col = "blue"), 6, 0, 0) )
shade3d( translate3d( dodecahedron3d(col = "cyan"), 9, 0, 0) )
shade3d( translate3d( icosahedron3d(col = "magenta"), 12, 0, 0) )

cylinder3d  

Create cylindrical or "tube" plots

Description

This function converts a description of a space curve into a "mesh3d" object forming a cylindrical tube around the curve.
cylinder3d
cylinder3d(center, radius = 1, twist = 0, e1 = NULL, e2 = NULL, e3 = NULL,
sides = 8, section = NULL, closed = 0,
rotationMinimizing = is.null(e2) & & is.null(e3),
debug = FALSE, keepVars = FALSE)

Arguments
center An n by 3 matrix whose columns are the x, y and z coordinates of the space
curve.
radius The radius of the cross-section of the tube at each point in the center.
twist The amount by which the polygon forming the tube is twisted at each point.
e1, e2, e3 The local coordinates to use at each point on the space curve. These default to a
rotation minimizing frame or Frenet coordinates.
sides The number of sides in the polygon cross section.
section The polygon cross section as a two-column matrix, or NULL.
closed Whether to treat the first and last points of the space curve as identical, and close
the curve, or put caps on the ends. See the Details.
rotationMinimizing Use a rotation minimizing local frame if TRUE, or a Frenet or user-specified
frame if FALSE.
debug If TRUE, plot the local Frenet coordinates at each point.
keepVars If TRUE, return the local variables in attribute "vars".

Details
The number of points in the space curve is determined by the vector lengths in center, after using
xyz.coords to convert it to a list. The other arguments radius, twist, e1, e2, and e3 are extended
to the same length.
The closed argument controls how the ends of the cylinder are handled. If closed > 0, it represents
the number of points of overlap in the coordinates. closed == TRUE is the same as closed = 1. If
closed > 0 but the ends don’t actually match, a warning will be given and results will be somewhat
unpredictable.
Negative values of closed indicate that caps should be put on the ends of the cylinder. If closed
== -1, a cap will be put on the end corresponding to center[1,]. If closed == -2, caps will be put
on both ends.
If section is NULL (the default), a regular sides-sided polygon is used, and radius measures the
distance from the center of the cylinder to each vertex. If not NULL, sides is ignored (and set
internally to nrow(section)), and radius is used as a multiplier to the vertex coordinates. twist
specifies the rotation of the polygon. Both radius and twist may be vectors, with values recycled
to the number of rows in center, while sides and section are the same at every point along the
curve.
The three optional arguments e1, e2, and e3 determine the local coordinate system used to create
the vertices at each point in center. If missing, they are computed by simple numerical approxima-
tions. e1 should be the tangent coordinate, giving the direction of the curve at the point. The
cross-section of the polygon will be orthogonal to e1. When rotationMinimizing is TRUE, e2 and e3 are chosen to give a rotation minimizing frame (see Wang et al., 2008). When it is FALSE, e2 defaults to an approximation to the normal or curvature vector; it is used as the image of the y axis of the polygon cross-section. e3 defaults to an approximation to the binormal vector, to which the x axis of the polygon maps. The vectors are orthogonalized and normalized at each point.

Value

A "mesh3d" object holding the cylinder, possibly with attribute "vars" containing the local environment of the function.

Author(s)

Duncan Murdoch

References

Examples

# A trefoil knot
open3d()
theta <- seq(0, 2*pi, len = 25)
knot <- cylinder3d(
  center = cbind(
    sin(theta) + 2*sin(2*theta),
    2*sin(3*theta),
    cos(theta) - 2*cos(2*theta)),
  e1 = cbind(
    cos(theta) + 4*cos(2*theta),
    6*cos(3*theta),
    sin(theta) + 4*sin(2*theta)),
  radius = 0.8,
  closed = TRUE)

shade3d(addNormals(subdivision3d(knot, depth = 2)), col = "green")

decorate3d

Add decorations to a 3D plot

decorate3d adds the usual decorations to a plot: labels, axes, etc.
drape3d

Usage

decorate3d(xlim = NULL, ylim = NULL, zlim = NULL,
  xlab = "x", ylab = "y", zlab = "z",
  box = TRUE, axes = TRUE,
  main = NULL, sub = NULL,
  top = TRUE, aspect = FALSE, expand = 1.03,
  tag = material3d("tag"), ...)

Arguments

xlim, ylim, zlim
These are used for the labels.

xlab, ylab, zlab
labels for the coordinates.

box, axes
whether to draw a box and axes.

main, sub
main title and subtitle.

top
whether to bring the window to the top when done.

aspect
either a logical indicating whether to adjust the aspect ratio, or a new ratio.

expand
how much to expand the box around the data, if it is drawn.

tag
optional label for objects being produced.

...
ignored.

Value

The RGL id values for those items.

Examples

open3d()
shade3d(tetrahedron3d(), col = "red")
decorate3d(main = "A Tetrahedron")

drape3d

Drape lines over a scene.

Description

Project a line onto the surface in a scene so that it appears to drape itself onto the surface.

Usage

drape3d(obj, ...)

## S3 method for class 'mesh3d'
drape3d(obj, x, y = NULL, z = NULL, plot = TRUE,
  up = c(0, 0, 1),
  P = projectDown(up), ...)

## Default S3 method:
drape3d(obj, ...)
Arguments

obj  The object(s) upon which to drape lines.

x, y, z  Coordinates of the line segments to be draped. Any reasonable way of defining the coordinates is acceptable. See the function \texttt{xyz.coords} for details.

plot  Should the result be plotted, or returned as a data frame?

up  The direction to consider as “up”.

P  The projection to use for draping, a 4x4 matrix.

...  For the “mesh3d” method, additional parameters to pass to \texttt{segments3d} when drawing the draped lines. For the “default” method, additional parameters to pass to the “mesh3d” method.

Details

The default method converts \texttt{obj} to a mesh using \texttt{as.mesh3d}, then uses the “mesh3d” method.

The current implementation constructs the segments to drape across the surface using the same method as \texttt{lines3d} uses: each successive point is joined to the previous one. Use \texttt{NA} coordinates to indicate breaks in the line.

The \texttt{P} matrix is used to project points to a plane as follows: They are transformed by \texttt{P} in homogeneous coordinates, then only first two (Euclidean) coordinates are kept.

Value

If \texttt{plot = TRUE}, plots the result and invisibly returns the object ID of the collection of segments.

If \texttt{plot = FALSE}, returns a matrix containing "x", "y" and "z" values for the line(s) (for use with \texttt{segments3d}).

Examples

```r
# volcano example taken from "persp"
#
z <- 2 * volcano  # Exaggerate the relief
x <- 10 * (1:nrow(z))  # 10 meter spacing (S to N)
y <- 10 * (1:ncol(z))  # 10 meter spacing (E to W)
zlim <- range(z)
```
colorlut <- terrain.colors(zlen) # height color lookup table

col <- colorlut[ z - zlim[1] + 1 ] # assign colors to heights for each point

open3d()

id <- surface3d(x, y, z, color = col, polygon_offset = 1)

segs <- data.frame(x = range(x) + c(100, -100),
                    y = range(y) + c(150, -100), z = 325)
drape3d(id, segs, col = 'yellow', lwd = 3)
lines3d(segs, col = 'red', lwd = 3)

p <- c(350, 205)       # (x,y) of strike & dip reading
off <- 20*c(-1, +1)    # X-marks-the-spot offset

segs <- data.frame(
                    x = c(p[1] + off, NA, p[1] + off),
                    z = rep(350, 5)
              )
drape3d(id, segs, col = "yellow", lwd = 3)

---

elementId2Prefix  Use widget with old-style controls

Description

The rglwidget control is designed to work in the htmlwidgets framework. Older RGL web pages that used writeWebGL or knitr used a different method of linking the controls to the scene. This is a partial bridge between the two systems. You should adopt the new system, not use this function.

Usage

elementId2Prefix(elementId, prefix = elementId)

Arguments

  elementId   An element identifier from a rglwidget call.
  prefix      The prefix to use in the old-style control.

Value

This function generates Javascript code, so it should be used in an results = "asis" block in a knitr document.

Author(s)

  Duncan Murdoch
**ellipse3d**

*Make an ellipsoid*

**Description**

A generic function and several methods returning an ellipsoid or other outline of a confidence region for three parameters.

**Usage**

```r
ellipse3d(x, ...)  
## Default S3 method: 
ellipse3d(x, scale = c(1, 1, 1), centre = c(0, 0, 0), level = 0.95,  
t = sqrt(qchisq(level, 3)), which = 1:3, subdivide = 3, smooth = TRUE, ...)  
## S3 method for class 'lm' 
ellipse3d(x, which = 1:3, level = 0.95, t = sqrt(3 * qf(level,  
3, x$df.residual)), ...)  
## S3 method for class 'glm' 
ellipse3d(x, which = 1:3, level = 0.95, t, dispersion, ...)  
## S3 method for class 'nls' 
ellipse3d(x, which = 1:3, level = 0.95, t = sqrt(3 * qf(level,  
3, s$df[2])), ...)```

**Arguments**

- `x` An object. In the default method the parameter `x` should be a square positive definite matrix at least 3x3 in size. It will be treated as the correlation or covariance of a multivariate normal distribution.
- `...` Additional parameters to pass to the default method or to `qmesh3d`.
- `scale` If `x` is a correlation matrix, then the standard deviations of each parameter can be given in the scale parameter. This defaults to c(1,1,1), so no rescaling will be done.
- `centre` The centre of the ellipse will be at this position.
- `level` The confidence level of a simultaneous confidence region. The default is 0.95, for a 95% region. This is used to control the size of the ellipsoid.
- `t` The size of the ellipse may also be controlled by specifying the value of a t-statistic on its boundary. This defaults to the appropriate value for the confidence region.
- `which` This parameter selects which variables from the object will be plotted. The default is the first 3.
- `subdivide` This controls the number of subdivisions (see `subdivision3d`) used in constructing the ellipsoid. Higher numbers give a smoother shape.
- `smooth` If TRUE, smooth interpolation of normals is used; if FALSE, a faceted ellipsoid will be displayed.
- `dispersion` The value of dispersion to use. If specified, it is treated as fixed, and chi-square limits for `t` are used. If missing, it is taken from `summary(x)`.
Value

A `mesh3d` object representing the ellipsoid.

Examples

```r
# Plot a random sample and an ellipsoid of concentration corresponding to a 95% # probability region for a # trivariate normal distribution with mean 0, unit variances and # correlation 0.8.
if (requireNamespace("MASS", quietly = TRUE)) {
  Sigma <- matrix(c(10, 3, 0, 3, 2, 0, 0, 0, 1), 3, 3)
  Mean <- 1:3
  x <- MASS::mvrnorm(1000, Mean, Sigma)

  open3d()
  plot3d(x, box = FALSE)

  plot3d( ellipse3d(Sigma, centre = Mean), col = "green", alpha = 0.5, add = TRUE)
}

# Plot the estimate and joint 90% confidence region for the displacement and cylinder # count linear coefficients in the mtcars dataset
data(mtcars)
fit <- lm(mpg ~ disp + cyl, mtcars)
open3d()
plot3d(ellipse3d(fit, level = 0.90), col = "blue", alpha = 0.5, aspect = TRUE)
```

Description

Gets the current scene using `scene3d`, and compares the result to a saved value, optionally closing the window afterwards.

Usage

```r
expect_known_scene(name, 
  close = TRUE, 
  file = paste0("testdata/", name, ".rds"), 
  ...)
```
Arguments

name        By default, the base name of the file to save results in. Not used if file is specified.
close      Whether to close the rgl window after the comparison.
file        The file in which to save the result.
...        Other arguments which will be passed to expect_known_value.

Details

This function uses expect_known_value to save a representation of the scene. During the comparison, the scene is modified so that non-reproducible aspects are standardized or omitted:

- object ids are changed to start at 1.
- system-specific font names and texture names are deleted.
- the window is shifted to the top left of the screen.

Calls to expect_known_scene() enable testthat::local_edition(2) for the duration of the call, so it will work in testthat “3rd edition”.

Value

A value describing the changes to the saved object, suitable for use in test_that().

Examples

```r
## Not run:
# These lines can be included in testthat::test_that() code.
plot3d(1:10, 1:10, 1:10)
expect_known_scene("plot")
## End(Not run)
```

extrude3d Generate extrusion mesh

Description

Given a two-dimensional polygon, this generates a three-dimensional extrusion of the shape by triangulating the polygon and creating a cylinder with that shape as the end faces.

Usage

```r
extrude3d(x, y = NULL, thickness = 1, smooth = FALSE, ...)
```
Arguments

- **x, y**: A polygon description in one of the forms supported by `triangulate`.
- **thickness**: The extrusion will have this thickness.
- **smooth**: logical; should normals be added so that the edges of the extrusion appear smooth?
- **...**: Other parameters to pass to `tmesh3d` when constructing the mesh.

Details

The extrusion is always constructed with the polygon in the xy plane at z = 0 and another copy at z = thickness. Use the transformation functions (e.g. `rotate3d`) to obtain other orientations and placements.

Value

A mesh object containing a triangulation of the polygon for each face, and quadrilaterals for the sides.

Author(s)

Duncan Murdoch

See Also

- `polygon3d` for a simple polygon, `triangulate` for the triangulation, `turn3d` for a solid of rotation.

Examples

```r
x <- c(1:10, 10:1)
y <- rev(c(rep(c(0, 2), 5), rep(c(1.5, -0.5), 5)))
plot(x, y, type = "n")
polygon(x, y)
open3d()
shade3d( extrude3d(x, y), col = "red" )
```

---

**facing3d**

*Subset an object to parts facing in a particular direction*

Description

facing3d subsets an object by converting it to a triangle mesh, then subsetting to those triangles that are counterclockwise (for `front = TRUE`) when projected into a plane.

`projectDown` computes a projection that “looks down” the specified direction.

---

**facing3d**

Subset an object to parts facing in a particular direction

Description

facing3d subsets an object by converting it to a triangle mesh, then subsetting to those triangles that are counterclockwise (for `front = TRUE`) when projected into a plane.

`projectDown` computes a projection that “looks down” the specified direction.
Usage

facing3d(obj, up = c(0, 0, 1),  
    P = projectDown(up),  
    front = TRUE, strict = TRUE)  
projectDown(up)

Arguments

obj    An object that can be converted to a triangular mesh object.
up     The direction that is to be considered “up”. It may be either a 3 vector in Eu-
      clidean coordinates or a 4 vector in homogeneous coordinates.
P      The projection to use for draping, a 4x4 matrix. See drape3d for details on how
       P is used.
front  If front = TRUE, retains triangles that are counterclockwise after projection by
       P, otherwise retains those that are clockwise.
strict If TRUE, drops indeterminate triangles (those that are annihilated by P).

Details

By default the returned subset will be those triangles whose upper side matches front. Change up
or use an arbitrary projection for different subsets.
drape3d and shadow3d project objects onto meshes; these functions can be used to project only
onto the top or front.

Value

facing3d returns a mesh object made of those triangles which face in the desired direction.
projectDown computes a 4x4 matrix. The first two coordinates of asEuclidean(x %*% projectDown(up))
give a projection of x from above into a plane, where up determines which direction is taken to be
“up”.

drape3d, shadow3d

Examples

open3d()

d <- rnorm(3)
d <- d/sqrt(sum(d^2))
shade3d( facing3d( icosahedron3d(), up = d, strict = FALSE),  
    col = "yellow")
wire3d( facing3d( icosahedron3d(), up = d, front = FALSE),  
    col = "black")
# Show the direction:
arrow3d(-2*d , -d)
figWidth

Get R Markdown figure dimensions in pixels

Description

In an R Markdown document, figure dimensions are normally specified in inches; these are translated into pixel dimensions when HTML output is requested and rglwidget is used. These functions reproduce that translation.

Usage

figWidth()
figHeight()

Value

When used in an R Markdown document, these functions return the requested current dimensions of figures in pixels. Outside such a document, NULL is returned.

Author(s)

Duncan Murdoch

Examples

# No useful return value outside of R Markdown:
figWidth()
figHeight()

gBoundary3d

Extract the boundary of a mesh

Description

Constructs a mesh of line segments corresponding to non-shared (i.e. boundary) edges of triangles or quads in the original mesh.

Usage

gBoundary3d(mesh, sorted = FALSE, simplify = TRUE)

Arguments

mesh A mesh object.
sorted Whether the result should have the segments sorted in sequential order.
simplify Whether to simplify the resulting mesh, dropping all unused vertices. If FALSE, the vertices of the result will be identical to the vertices of mesh; if TRUE, they will likely be different, even if no vertices were dropped.
GramSchmidt

Value

A "mesh3d" object containing 0 or more segments.

Author(s)

Duncan Murdoch

See Also

t mesh3d

Examples

x <- cube3d()
x$ib <- x$ib[, -(1:2)]
b <- getBoundary3d(x, sorted = TRUE)

open3d()
shade3d(x, alpha=0.2, col = "blue")
shade3d(b)

# Show edge vertices in sequence:
text3d(t(b$vb), text = 1:ncol(b$vb), adj = 0)
c(b$is[1,], b$is[2,])

GramSchmidt

The Gram-Schmidt algorithm

Description

Generate a 3x3 orthogonal matrix using the Gram-Schmidt algorithm.

Usage

GramSchmidt(v1, v2, v3, order = 1:3)

Arguments

v1, v2, v3 Three length 3 vectors (taken as row vectors).
order The precedence order for the vectors; see Details.

Details

This function orthogonalizes the matrix rbind(v1, v2, v3) using the Gram-Schmidt algorithm. It can handle rank 2 matrices (returning a rank 3 matrix). If the original is rank 1, it is likely to fail.

The order vector determines the precedence of the original vectors. For example, if it is c(i, j, k), then row i will be unchanged (other than normalization); row j will normally be transformed within the span of rows i and j. Row k will be transformed orthogonally to the span of the others.
Value

A 3x3 matrix whose rows are the orthogonalization of the original row vectors.

Author(s)

Duncan Murdoch

Examples

# Proceed through the rows in order
print(A <- matrix(rnorm(9), 3, 3))
GramSchmidt(A[1, ], A[2, ], A[3, ])

# Keep the middle row unchanged
print(A <- matrix(c(rnorm(2), 0, 1, 0, 0, rnorm(3)), 3, 3, byrow = TRUE))
GramSchmidt(A[1, ], A[2, ], A[3, ], order = c(2, 1, 3))

grid3d

Add a grid to a 3D plot

Description

This function adds a reference grid to an RGL plot.

Usage

grid3d(side, at = NULL, col = "gray", lwd = 1, lty = 1, n = 5)

Arguments

side Where to put the grid; see the Details section.
at How to draw the grid; see the Details section.
col The color of the grid lines.
lwd The line width of the grid lines. (Currently only lty = 1 is supported.)
lty The line type of the grid lines.
n Suggested number of grid lines; see the Details section.

Details

This function is similar to grid in classic graphics, except that it draws a 3D grid in the plot.

The grid is drawn in a plane perpendicular to the coordinate axes. The first letter of the side argument specifies the direction of the plane: "x", "y" or "z" (or uppercase versions) to specify the coordinate which is constant on the plane.

If at = NULL (the default), the grid is drawn at the limit of the box around the data. If the second letter of the side argument is "-" or is not present, it is the lower limit; if "+" then at the upper
limit. The grid lines are drawn at values chosen by `pretty` with `n` suggested locations. The default locations should match those chosen by `axis3d` with `nticks = n`.

If `at` is a numeric vector, the grid lines are drawn at those values.

If `at` is a list, then the "x" component is used to specify the x location, the "y" component specifies the y location, and the "z" component specifies the z location. Missing components are handled using the default as for `at = NULL`.

Multiple grids may be drawn by specifying multiple values for `side` or for the component of `at` that specifies the grid location.

**Value**

A vector or matrix of object ids is returned invisibly.

**Note**

If the scene is resized, the grid will not be resized; use `abclines3d` to draw grid lines that will automatically resize.

**Author(s)**

**See Also**

`axis3d`

**Examples**

```r
x <- 1:10
y <- 1:10
z <- matrix(outer(x - 5, y - 5) + rnorm(100), 10, 10)
open3d()
persp3d(x, y, z, col = "red", alpha = 0.7, aspect = c(1, 1, 0.5))
grid3d(c("x", "y+", "z"))
```

---

**identify3d**

*Identify points in plot*

**Description**

Identify points in a plot, similarly to the `identify` function in base graphics.

**Usage**

```r
identify3d(x, y = NULL, z = NULL, labels = seq_along(x), n = length(x),
plot = TRUE, adj = c(-0.1, 0.5), tolerance = 20,
buttons = c("right", "middle"))
```
Arguments

x, y, z  coordinates of points in a scatter plot. Alternatively, any object which defines coordinates (see `xyz.coords`) can be given as x, and y and z left missing.

labels  an optional character vector giving labels for the points. Will be coerced using `as.character`, and recycled if necessary to the length of x.

n  the maximum number of points to be identified.

plot  logical: if plot is TRUE, the labels are printed near the points and if FALSE they are omitted.

adj  numeric vector to use as adj parameter to `text3d` when plotting the labels.

tolerance  the maximal distance (in pixels) for the pointer to be ‘close enough’ to a point.

buttons  a length 1 or 2 character vector giving the buttons to use for selection and quitting.

Details

If `buttons` is length 1, the user can quit by reaching n selections, or by hitting the escape key, but the result will be lost if escape is used.

Value

A vector of selected indices.

Author(s)

Duncan Murdoch

See Also

`identify` for base graphics, `select3d` for selecting regions.

---

Description

This object is imported from `magrittr`. Follow the link to its documentation.

`magrittr %>%`

Pipes can be used to string together `rglwidget` calls and `playwidget` calls. See `ageControl` for an example.
in_pkgdown_example  Are we running in a **pkgdown** example?

---

**Description**

This is mainly for internal use to decide whether results should be automatically included in a **pkgdown** web page.

**Usage**

```r
in_pkgdown_example()
```

**Value**

`TRUE` or `FALSE`

**Examples**

```r
in_pkgdown_example()
```

---

**light**  
*Add light source*

---

**Description**

add a light source to the scene.

**Usage**

```r
ligh3d(theta = 0, phi = 15, x = NULL, ...)
rgl.light( theta = 0, phi = 0, viewpoint.rel = TRUE, ambient = "#FFFFFF",
diffuse = "#FFFFFF", specular = "#FFFFFF", x = NULL, y = NULL, z = NULL)
```

**Arguments**

- `theta, phi`  polar coordinates, used by default
- `viewpoint.rel`  logical, if TRUE light is a viewpoint light that is positioned relative to the current viewpoint
- `ambient, diffuse, specular`  light color values used for lighting calculation
- `x, y, z`  cartesian coordinates, optional
- `...`  generic arguments passed through to RGL-specific (or other) functions
Details

Up to 8 light sources are supported. They are positioned either in world space or relative to the camera. By providing polar coordinates to theta and phi a directional light source is used. If numerical values are given to x, y and z, a point-like light source with finite distance to the objects in the scene is set up.

If x is non-null, \texttt{xyz.coords} will be used to form the location values, so all three coordinates can be specified in x.

See \texttt{material3d} for a discussion of how the components of the light affect the display of objects.

Value

This function is called for the side effect of adding a light. A light ID is returned to allow \texttt{pop3d} to remove it.

See Also

\texttt{rgl.clear pop3d}

Examples

```r
# a lightsource moving through the scene
#
data(volcano)
z <- 2 * volcano # Exaggerate the relief
x <- 10 * (1:nrow(z)) # 10 meter spacing (S to N)
y <- 10 * (1:ncol(z)) # 10 meter spacing (E to W)
zlim <- range(z)
colorlut <- terrain.colors(zlen) # height color lookup table
col <- colorlut[ z - zlim[1] + 1 ] # assign colors to heights for each point

open3d()
bg3d(“gray50”)
surface3d(x, y, z, color = col, back = “lines”)
r <- max(y) - mean(y)
lightid <- spheres3d(1, 1, 1, alpha = 0)
frame <- function(time) {
  a <- pi*(time - 1)
  save <- par3d(skipRedraw = TRUE)
clear3d(type = “lights”)
  pop3d(id = lightid)
  xyz <- matrix(c(r*sin(a) + mean(x), r*cos(a) + mean(y), max(z)), ncol = 3)
light3d(x = xyz, diffuse = “gray75”,
         specular = “gray75”, viewpoint.rel = FALSE)
light3d(diffuse = “gray10”, specular = “gray25”)
  lightid <<- spheres3d(xyz, emission = “white”, radius = 4)
par3d(save)
Sys.sleep(0.02)
```
makeDependency

```r
makeDependency(NULL, package = package, version = packageVersion(package),
               minifile = paste0(basename(src), ".min.js"),
               debug = FALSE, ...)
```

**Arguments**

- `name`, `src`, `script = NULL`, `package`, `version = packageVersion(package)`, `minifile = paste0(basename(src), ".min.js"),
  `debugging = FALSE, ...`
- `minifile` Basename of minified file.
- `debugging` See details below.

**Details**

This is a utility function used by RGL to process its Javascript code used when displaying `rglwidget` values. It may be helpful in other packages to use in their own installation.

If the `js` package version 1.2 or greater is installed, the Javascript code will be minified and stored in the file named by `minifile` in the `src` directory. Syntax errors in the code will stop the process; unused variables will be reported.

If debugging is `TRUE`, the locations of Javascript syntax errors will be reported, along with hints about improvements, and the original files will be used in the dependency object that is created.

If debugging is `FALSE` (the default), the minified file will be used in the dependency object, hints won’t be given, and syntax errors will lead to an uninformative failure to minify.

**Value**

An object that can be included in a list of dependencies passed to `htmltools::attachDependencies`.

**Author(s)**

Duncan Murdoch
matrices

**Work with homogeneous coordinates**

matrices

Description

These functions construct 4x4 matrices for transformations in the homogeneous coordinate system used by OpenGL, and translate vectors between homogeneous and Euclidean coordinates.

Usage

- `identityMatrix()`
- `scaleMatrix(x, y, z)`
- `translationMatrix(x, y, z)`
- `rotationMatrix(angle, x, y, z, matrix)`
- `asHomogeneous(x)`
- `asEuclidean(x)`
- `asHomogeneous2(x)`
- `asEuclidean2(x)`
scale3d(obj, x, y, z, ...)  
translate3d(obj, x, y, z, ...)  
rotate3d(obj, angle, x, y, z, matrix, ...)  
transform3d(obj, matrix, ...)

Arguments

x, y, z, angle, matrix  
See details  
obj  
An object to be transformed  
...  
Additional parameters to be passed to methods

Details

OpenGL uses homogeneous coordinates to handle perspective and affine transformations. The homogeneous point \((x, y, z, w)\) corresponds to the Euclidean point \((x/w, y/w, z/w)\). The matrices produced by the functions scaleMatrix, translationMatrix, and rotationMatrix are to be left-multiplied by a row vector of homogeneous coordinates; alternatively, the transpose of the result can be right-multiplied by a column vector. The generic functions scale3d, translate3d and rotate3d apply these transformations to the \(obj\) argument. The transform3d function is a synonym for rotate3d(obj, matrix = matrix).

By default, it is assumed that \(obj\) is a row vector (or a matrix of row vectors) which will be multiplied on the right by the corresponding matrix, but users may write methods for these generics which operate differently. Methods are supplied for mesh3d objects.

To compose transformations, use matrix multiplication. The effect is to apply the matrix on the left first, followed by the one on the right.

identityMatrix returns an identity matrix.

scaleMatrix scales each coordinate by the given factor. In Euclidean coordinates, \((u, v, w)\) is transformed to \((x*u, y*v, z*w)\).

translationMatrix translates each coordinate by the given translation, i.e. \((u, v, w)\) is transformed to \((u + x, v + y, w + z)\).

rotationMatrix can be called in three ways. With arguments \(angle, x, y, z\) it represents a rotation of \(angle\) radians about the axis \(x, y, z\). If \(matrix\) is a 3x3 rotation matrix, it will be converted into the corresponding matrix in 4x4 homogeneous coordinates. Finally, if a 4x4 matrix is given, it will be returned unchanged. (The latter behaviour is used to allow transform3d to act like a generic function, even though it is not.)

Use asHomogeneous(x) to convert the Euclidean vector \(x\) to homogeneous coordinates, and asEuclidean(x) for the reverse transformation. These functions accept the following inputs:

- \(n \times 3\) matrices: rows are assumed to be Euclidean
- \(n \times 4\) matrices: rows are assumed to be homogeneous
• vectors of length 3n or 4n: assumed to be vectors concatenated. For the ambiguous case of vectors that are length 12n (so both 3n and 4n are possible), the assumption is that the conversion is necessary: asEuclidean assumes the vectors are homogeneous, and asHomogeneous assumes the vectors are Euclidean.

Outputs are n x 4 or n x 3 matrices for asHomogeneous and asEuclidean respectively.

The functions asHomogeneous2 and asEuclidean2 act similarly, but they assume inputs are 3 x n or 4 x n and outputs are in similar shapes.

Value

identityMatrix, scaleMatrix, translationMatrix, and rotationMatrix produce a 4x4 matrix representing the requested transformation in homogeneous coordinates.

scale3d, translate3d and rotate3d transform the object and produce a new object of the same class.

Author(s)

Duncan Murdoch

See Also

par3d for a description of how RGL uses matrices in rendering.

Examples

# A 90 degree rotation about the x axis:
rotationMatrix(pi/2, 1, 0, 0)

# Find what happens when you rotate (2, 0, 0) by 45 degrees about the y axis:

x <- asHomogeneous(c(2, 0, 0))
y <- x %*% rotationMatrix(pi/4, 0, 1, 0)
asEuclidean(y)

# or more simply...

rotate3d(c(2, 0, 0), pi/4, 0, 1, 0)
mergeVertices

Usage

## S3 method for class 'mesh3d'
merge(x, y, ..., attributesMustMatch = FALSE)

Arguments

x, y
"mesh3d" objects to merge.
...
Optional additional objects.
attributesMustMatch
See Details.

Details

To allow objects to be merged, they need to be similar enough in terms of having the same list of material properties, normals, texture coordinates, etc.

If attributesMustMatch is TRUE, it is an error to have attributes in one mesh but not in another, and those attributes that only specify a single value must have equal values in all meshes.

If attributesMustMatch is FALSE, any non-matching attributes will be dropped from the final result.

Value

A single "mesh3d" object merging the contents of the arguments.

Author(s)

Duncan Murdoch

Examples

open3d()
# Notice that the alpha setting for the cube is dropped, because
# the other shapes don't specify alpha.
shade3d(merge(cube3d(col="red", alpha = 0.5),
              translate3d(tetrahedron3d(col="green"), 2, 0, 0),
              translate3d(octahedron3d(col="blue"), 4, 0, 0)))

mergeVertices

Description

A mesh object can have the same vertex listed twice. Each copy is allowed to have separate normals, texture coordinates, and color. However, it is more efficient to have just a single copy if those differences aren't needed. For automatic smoothing using addNormals, triangles and quads need to share vertices. This function merges identical (or similar) vertices to achieve this.
Usage

mergeVertices(mesh,
            notEqual = NULL,
            attribute = "vertices",
            tolerance = sqrt(.Machine$double.eps))

Arguments

mesh A mesh3d object.
notEqual A logical matrix indicating that certain pairs should not be merged even if they appear identical.
attribute Which attribute(s) should be considered in comparing vertices? A vector chosen from c("vertices", "colors", "normals", "texcoords")
tolerance When comparing vertices using all.equal, this tolerance will be used to ignore rounding error.

Value

A new mesh object.

Author(s)

Duncan Murdoch

See Also

as.mesh3d.rglId, which often constructs mesh objects containing a lot of duplication.

Examples

open3d()
(mesh1 <- cuboctahedron3d(col = rainbow(14), meshColor = "face"))
id <- shade3d(mesh1)
(mesh2 <- as.mesh3d(id))
shade3d(translate3d(mesh2, 3, 0, 0))
(mesh3 <- mergeVertices(mesh2))
shade3d(translate3d(mesh3, 6, 0, 0))
Usage

```r
mesh3d( x, y = NULL, z = NULL, vertices,
       material = NULL,
       normals = NULL, texcoords = NULL,
       points = NULL, segments = NULL,
       triangles = NULL, quads = NULL,
       meshColor = c("vertices", "edges", "faces", "legacy"))
qmesh3d(vertices, indices, homogeneous = TRUE, material = NULL,
        normals = NULL, texcoords = NULL,
        meshColor = c("vertices", "edges", "faces", "legacy"))
tmesh3d(vertices, indices, homogeneous = TRUE, material = NULL,
        normals = NULL, texcoords = NULL,
        meshColor = c("vertices", "edges", "faces", "legacy"))
```

Arguments

- `x, y, z` coordinates. Any reasonable way of defining the coordinates is acceptable. See the function `xyz.coords` for details.
- `vertices` A 4 row matrix of homogeneous coordinates; takes precedence over `x, y, z`.
- `material` material properties for later rendering
- `normals` normals at each vertex
- `texcoords` texture coordinates at each vertex
- `points` vector of indices of vertices to draw as points
- `segments` 2 x n matrix of indices of vertices to draw as segments
- `triangles` 3 x n matrix of indices of vertices to draw as triangles
- `quads` 4 x n matrix of indices of vertices to draw as quads
- `indices` (obsolete) 3 or 4 x n matrix of vertex indices
- `homogeneous` (obsolete) should `tmesh3d` and `qmesh3d` vertices be assumed to be homogeneous?
- `meshColor` how should colours be interpreted? See details in `shade3d`.

Details

These functions create `mesh3d` objects, which consist of a matrix of vertex coordinates together with a matrices of indices indicating how the vertices should be displayed, and material properties.

The "shape3d" class is a general class for shapes that can be plotted by `dot3d, wire3d` or `shade3d`.

The "mesh3d" class is a class of objects that form meshes: the vertices are in member `vb`, as a 4 by n matrix using homogeneous coordinates. Indices of these vertices are contained in optional components `ip` for points, `is` for line segments, `it` for triangles, and `ib` for quads. Individual meshes may have any combination of these.

The functions `tmesh3d` and `qmesh3d` are included for back-compatibility; they produce meshes of triangles and quads respectively.
Value

Objects of class c("mesh3d","shape3d").
See rgl.primitive for a discussion of texture coordinates.

See Also

shade3d, shapelist3d for multiple shapes

Examples

# generate a quad mesh object
vertices <- c(
  -1.0, -1.0, 0,
  1.0, -1.0, 0,
  1.0, 1.0, 0,
  -1.0, 1.0, 0
)
indices <- c( 1, 2, 3, 4 )

open3d()
wire3d( mesh3d(vertices = vertices, quads = indices) )
Arguments

value:
A new subscene list to set. If missing, return the current one (or NULL).

window:
Which window to operate on.

nr, nc:
Number of rows and columns of figures.

byrow:
Whether figures progress by row (as with `par("mfrow")`) or by column (as with `par("mfcol")`).

mat, widths, heights:
Layout parameters; see `layout` for their interpretation.

parent:
The parent subscene. NA indicates the current subscene. See Details below.

sharedMouse:
Whether to make all subscenes `par3d("listeners")` to each other.

...:
Additional parameters to pass to `newSubscene3d` as each subscene is created.

current:
The subscene to move away from. NA indicates the current subscene.

clear:
Whether the newly entered subscene should be cleared upon entry.

reuse:
Whether to skip advancing if the current subscene has no objects in it.

delete:
If TRUE, delete the subscenes in the current window.

Details

`rgl` can maintain a list of subscenes; the `mfrow3d` and `layout3d` functions create that list. When the list is in place, `next3d` causes RGL to move to the next scene in the list, or cycle back to the first one.

Unlike the classic R graphics versions of these functions, these functions are completely compatible with each other. You can mix them within a single RGL window.

In the default case where `parent` is missing, `mfrow3d` and `layout3d` will call `clearSubsceneList()` at the start.

By default `clearSubsceneList()` checks whether the current subscene is in the current subscene list; if so, it will delete all subscenes in the list, and call `gc3d` to delete any objects that are no longer shown. The subscene list will be set to a previous value if one was recorded, or NULL if not.

If `parent` is specified in `mfrow3d` or `layout3d` (even as NA), the new subscenes will be created within the parent.

The `next3d()` function first finds out if the current subscene is in the current list. If not, it moves to the previous list, and looks there. Once it finds a list containing the current subscene, it moves to the next entry in that list. If it can’t find one, it creates a length one list containing just the current subscene.

Value

`mfrow3d` and `layout3d` return a vector of subscene id values that have just been created. If a previous subscene list was in effect and was not automatically cleared, it is attached as an attribute "prev".

observer3d

**See Also**

`newSubscene3d`, `par`, `layout`.

**Examples**

```r
shapes <- list(Tetrahedron = tetrahedron3d(), Cube = cube3d(), Octahedron = octahedron3d(),
               Icosahedron = icosahedron3d(), Dodecahedron = dodecahedron3d(),
               Cuboctahedron = cuboctahedron3d())
col <- rainbow(6)
open3d()
mfrow3d(3, 2)
for (i in 1:6) {
  next3d() # won't advance the first time, since it is empty
  shade3d(shapes[[i]], col = col[i])
}
highlevel(integer()) # To trigger display as rglwidget

open3d()
mat <- matrix(1:4, 2, 2)
mat <- rbind(mat, mat + 4, mat + 8)
layout3d(mat, height = rep(c(3, 1), 3), sharedMouse = TRUE)
for (i in 1:6) {
  next3d()
  shade3d(shapes[[i]], col = col[i])
  next3d()
  text3d(0, 0, 0, names(shapes)[i])
}
highlevel(integer())
```

---

**observer3d**

*Set the observer location*

**Description**

This function sets the location of the viewer.

**Usage**

```r
observer3d(x, y = NULL, z = NULL, auto = FALSE)
```

**Arguments**

- `x, y, z` The location as a 3 vector, using the usual `xyz.coords` conventions for specification. If `x` is missing or any coordinate is `NA`, no change will be made to the location.
- `auto` If `TRUE`, the location will be set automatically by RGL to make the whole bounding box visible.
open3d

Details

This function sets the location of the viewer relative to the scene, after the model transformations (scaling, rotation) have been done, but before lighting or projection have been applied. (See par3d for details on the rendering pipeline.)

The coordinate system is a slightly strange one: the X coordinate moves the observer location from left to right, and the Y coordinate moves up and down. The Z coordinate changes the depth from the viewer. All are measured relative to the center of the bounding box (par("bbox")) of the subscene. The observer always looks in the positive Z direction after the model rotation have been done. The coordinates are in post-scaling units.

Value

Invisibly returns the previous value.

Note

This function is likely to change in future versions of RGL, to allow more flexibility in the specification of the observer’s location and orientation.

Duncan Murdoch

Examples

example(surface3d)  # The volcano data
observer3d(0, 0, 440)  # Viewed from very close up

Description

open3d opens a new RGL window; cur3d returns the device number of the current window; close3d closes one or more windows.

Usage

open3d(..., params = getr3dDefaults(),
useNULL = rgl.useNULL(), silent = FALSE)

close3d(dev = cur3d(), silent = TRUE)

cur3d()

set3d(dev, silent = FALSE)
getr3dDefaults(class = NULL, value = NULL)

r3dDefaults

Arguments

... arguments in name = value form, or a list of named values. The names must come from the graphical parameters described in par3d.

params a list of graphical parameters

useNULL whether to use the null graphics device
dev which device to close or use

silent whether report on what was done
class, value names of components to retrieve

Details

open3d opens a new RGL device, and sets the parameters as requested. The r3dDefaults list returned by the getr3dDefaults function will be used as default values for parameters. As installed this sets the point of view to 'world coordinates' (i.e. x running from left to right, y from front to back, z from bottom to top), the mouseMode to (zAxis, zoom, fov), and the field of view to 30 degrees. useFreeType defaults to FALSE on Windows; on other systems it indicates the availability of FreeType. Users may create their own variable named r3dDefaults in the global environment and it will override the installed one. If there is a bg element in the list or the arguments, it should be a list of arguments to pass to the bg3d function to set the background.

The arguments to open3d may include material, a list of material properties as in r3dDefaults, but note that high level functions such as plot3d normally use the r3dDefaults values in preference to this setting.

If useNULL is TRUE, RGL will use a “null” device. This device records objects as they are plotted, but displays nothing. It is intended for use with rglwidget.

Value

The open3d function returns the device that was opened. If silent = TRUE, it is returned invisibly.

The cur3d function returns the current device, or the value 0 if there isn’t one.

set3d returns the device number of the previously active device.

The close3d function returns the new current device, invisibly.

The r3dDefaults variable is a list containing default settings. The getr3dDefaults function searches the user’s global environment for r3dDefaults and returns the one in the RGL namespace if it was not found there. The components of the list may include any settable par3d parameter, or "material", which should include a list of default material3d properties, or "bg", which is a list of defaults to pass to the bg3d function.

See Also

rgl.useNULL for default usage of null device.
Examples

```r
r3dDefaults
open3d()
shade3d(cube3d(color = rainbow(6), meshColor = "faces"))
cur3d()
```

---

**par3d**

*Set or query RGL parameters*

---

**Description**

`par3d` can be used to set or query graphical parameters in RGL. Parameters can be set by specifying them as arguments to `par3d` in `name = value` form, or by passing them as a list of named values.

**Usage**

```r
par3d(..., no.readonly = FALSE, dev = cur3d(),
        subscene = currentSubscene3d(dev))
```

**Arguments**

- `...`: arguments in `name = value` form, or a list of tagged values. The names must come from the graphical parameters described below.
- `no.readonly`: logical; if `TRUE` and there are no other arguments, only those parameters which can be set by a subsequent `par3d()` call are returned.
- `dev`: integer; the RGL device.
- `subscene`: integer; the subscene.

**Details**

Parameters are queried by giving one or more character vectors to `par3d`.

- `par3d()` (no arguments) or `par3d(no.readonly = TRUE)` is used to get *all* the graphical parameters (as a named list).

By default, queries and modifications apply to the current subscene on the current device; specify `dev` and/or `subscene` to change this. Some parameters apply to the device as a whole; these are marked in the list below.

**Value**

When parameters are set, their former values are returned in an invisible named list. Such a list can be passed as an argument to `par3d` to restore the parameter values. Use `par3d(no.readonly = TRUE)` for the full list of parameters that can be restored.

When just one parameter is queried, its value is returned directly. When two or more parameters are queried, the result is a list of values, with the list names giving the parameters.

Note the inconsistency: setting one parameter returns a list, but querying one parameter returns an object.
Parameters

R.O. indicates read-only arguments: These may only be used in queries, i.e., they do not set anything.

activeSubscene R.O. integer. Used with rgl.setMouseCallbacks: during a callback, indicates the id of the subscene that was clicked.

antialias R.O. in par3d, may be set in open3d. The (requested) number of hardware antialiasing planes to use (with multisample antialiasing). The OpenGL driver may not support the requested number, in which case par3d("antialias") will report what was actually set. Applies to the whole device.

cex real. The default size for text.

cFamily character. The default device independent family name; see rgl.texts. Applies to the whole device.

font integer. The default font number (from 1 to 4; see rgl.texts). Applies to the whole device.

useFreeType logical. Should FreeType fonts be used? Applies to the whole device.

fontName R.O.; the system-dependent name of the current font. Applies to the whole device.

FOV real. The field of view, from 0 to 179 degrees. This controls the degree of parallax in the perspective view. Isometric perspective corresponds to FOV = 0.

ignoreExtent logical. Set to TRUE so that subsequently plotted objects will be ignored in calculating the bounding box of the scene. Applies to the whole device.

maxClipPlanes R.O.; an integer giving the maximum number of clip planes that can be defined in the current system. Applies to the whole device.

modelMatrix R.O.; a 4 by 4 matrix describing the position of the user data. See the Note below.

listeners integer. A vector of subscene id values. If a subscene receives a mouse event (see mouseMode just below), the same action will be carried out on all subscenes in this list. (The subscene itself is normally listed as a listener. If it is not listed, it will not respond to its own mouse events.)

mouseMode character. A vector of 5 strings describing mouse actions. The 5 entries are named c("none","left","right","middle","wheel"), corresponding to actions for no button, the left, right or middle button, and the mouse wheel. Partial matching to action names is used. Possible values for the actions are:

"none" No action for this button.
"trackball" Mouse acts as a virtual trackball, rotating the scene.
"yAxis" Similar to "trackball", but restricted to Y axis rotation.
"zAxis" Y axis rotation.
"polar" Mouse rotates the scene by moving in polar coordinates.
"selecting" Mouse is used for selection. This is not normally set by the user, but is used internally by the select3d function.
"zoom" Mouse is used to zoom the display.
"fov" Mouse changes the field of view of the display.
"user" Used when a user handler is set by rgl.setMouseCallbacks.

Possible values for the last entry corresponding to the mouse wheel also include
"pull" Pulling on the mouse wheel increases magnification, i.e. "pulls the scene closer".
"push" Pulling on the mouse wheel decreases magnification, i.e. "pushes the scene away".
"user2" Used when a user handler is set by \texttt{rgl.setWheelCallback}.

A common default on Mac OSX is to convert a two finger drag on a trackpad to a mouse wheel rotation.

The first entry is for actions to take when no mouse button is pressed. Legal values are the same as for the mouse buttons.

The first entry was added after \texttt{rgl} version 0.106.8. For back compatibility, if the vector of actions is less than 5 entries, "none" will be added at the start of it.

\texttt{observer} \texttt{R.O.}; the position of the observer relative to the model. Set by \texttt{observer3d}. See the Note below.

\texttt{projMatrix} \texttt{R.O.}; a 4 by 4 matrix describing the current projection of the scene.

\texttt{scale} real. A vector of 3 values indicating the amount by which to rescale each axis before display. Set by \texttt{aspect3d}.

\texttt{skipRedraw} whether to update the display. Set to \texttt{TRUE} to suspend updating while making multiple changes to the scene. See \texttt{demo(hist3d)} for an example. Applies to the whole device.

\texttt{userMatrix} a 4 by 4 matrix describing user actions to display the scene.

\texttt{userProjection} a 4 by 4 matrix describing changes to the projection.

\texttt{viewport} real. A vector giving the dimensions of the window in pixels. The entries are taken to be \(c(x,y,\text{width}, \text{height})\) where \(c(x,y)\) are the coordinates in pixels of the lower left corner within the window.

\texttt{zoom} real. A positive value indicating the current magnification of the scene.

\texttt{bbox} \texttt{R.O.}; real. A vector of six values indicating the current values of the bounding box of the scene \((\text{xmin}, \text{xmax}, \text{ymin}, \text{ymax}, \text{zmin}, \text{zmax})\).

\texttt{windowRect} integer. A vector of four values indicating the left, top, right and bottom of the displayed window (in pixels). Applies to the whole device.

\textbf{Rendering}

The parameters returned by \texttt{par3d} are sufficient to determine where RGL would render a point on the screen. Given a column vector \((x,y,z)\) in a subscene \(s\), it performs the equivalent of the following operations:

1. It converts the point to homogeneous coordinates by appending \(w = 1\), giving the vector \(v = (x,y,z,1)\).
2. It calculates the \(M = \texttt{par3d("modelMatrix")}\) as a product from right to left of the following matrices:
   - A matrix to translate the centre of the bounding box to the origin.
   - A matrix to rescale according to \texttt{par3d("scale")}.
   - The \texttt{par3d("userMatrix")} as set by the user.
   - A matrix which may be set by mouse movements.
   - If \(s\) has the "model" set to "modify", a similar collection of matrices using parameters from the parent subscene.
3. It multiplies the point by \(M\) giving \(u = M \times v\).
4. It multiplies that point by a matrix based on the observer position to translate the origin to the centre of the viewing region.

5. Using this location and information on the normals (which have been similarly transformed), it performs lighting calculations.

6. It obtains the projection matrix \( P = \text{par3d}("projMatrix") \) based on the bounding box and field of view or observer location, multiplies that by the userProjection matrix to give \( P \). It multiplies the point by it giving \( P \cdot u = (x_2, y_2, z_2, w_2) \).

7. It converts back to Euclidean coordinates by dividing the first 3 coordinates by \( w_2 \).

8. The new value \( z_2/w_2 \) represents the depth into the scene of the point. Depending on what has already been plotted, this depth might be obscured, in which case nothing more is plotted.

9. If the point is not culled due to depth, the \( x_2 \) and \( y_2 \) values are used to determine the point in the image. The \( \text{par3d}("viewport") \) values are used to translate from the range \((-1, 1)\) to pixel locations, and the point is plotted.

10. If hardware antialiasing is enabled, then the whole process is repeated multiple times (at least conceptually) with different locations in each pixel sampled to determine what is plotted there, and then the images are combined into what is displayed.

See `?matrices` for more information on homogeneous and Euclidean coordinates.

Note that many of these calculations are done on the graphics card using single precision; you will likely see signs of rounding error if your scene requires more than 4 or 5 digit precision to distinguish values in any coordinate.

**Note**

The "xAxis", "yAxis" and "zAxis" mouse modes rotate relative to the coordinate system of the data, regardless of the current orientation of the scene.

When multiple parameters are set, they are set in the order given. In some cases this may lead to warnings and ignored values; for example, some font families only support \( \text{cex} = 1 \), so changing both \( \text{cex} \) and \( \text{family} \) needs to be done in the right order. For example, when using the "bitmap" family on Windows, \( \text{par3d}(\text{family} = \text{"sans"}, \text{cex} = 2) \) will work, but \( \text{par3d}(\text{cex} = 2, \text{family} = \text{"sans"}) \) will leave \( \text{cex} \) at 1 (with a warning that the "bitmap" family only supports that size).

Although \( \text{par3d}(\text{"viewport"}) \) names the entries of the reported vector, names are ignored when setting the viewport and entries must be specified in the standard order.

In `rgl` versions 0.94.x the `modelMatrix` entry had a changed meaning; before and after that it contains a copy of the OpenGL MODELVIEW matrix.

As of version 0.100.32, when changing the "windowRect" parameter, the "viewport" for the root (or specified) subscene is changed immediately. This fixes a bug where in earlier versions it would only be changed when the window was redrawn, potentially after another command making use of the value.

Default values are not described here, as several of them are changed by the `r3dDefaults` variable when the window is opened by `open3d`.

Examples

```r
open3d()
shade3d(cube3d(color = rainbow(6), meshColor = "faces"))
save <- par3d(userMatrix = rotationMatrix(90*pi/180, 1, 0, 0))
highlevel() # To trigger display
save
par3d("userMatrix")
par3d(save)
highlevel()
par3d("userMatrix")
```

---

`par3dinterp`  
*Interpolator for par3d parameters*

Description

Returns a function which interpolates `par3d` parameter values, suitable for use in animations.

Usage

```r
par3dinterp(times = NULL, userMatrix, scale, zoom, FOV,
method = c("spline", "linear"),
extrapolate = c("oscillate", "cycle", "constant", "natural"),
dev = cur3d(), subscene = par3d("listeners", dev = dev))
```

Arguments

- `times` Times at which values are recorded or a list; see below
- `userMatrix` Values of `par3d("userMatrix")`
- `scale` Values of `par3d("scale")`
- `zoom` Values of `par3d("zoom")`
- `FOV` Values of `par3d("FOV")`
- `method` Method of interpolation
- `extrapolate` How to extrapolate outside the time range
- `dev` Which RGL device to use
- `subscene` Which subscene to use
Details

This function is intended to be used in constructing animations. It produces a function that returns a list suitable to pass to `par3d`, to set the viewpoint at a given point in time.

All of the parameters are optional. Only those `par3d` parameters that are specified will be returned. The input values other than `times` may each be specified as lists, giving the parameter value settings at a fixed time, or as matrices or arrays. If not lists, the following formats should be used: `userMatrix` can be a $4 \times 4 \times n$ array, or a $4 \times 4n$ matrix; `scale` should be an $n \times 3$ matrix; `zoom` and `FOV` should be length $n$ vectors.

An alternative form of input is to put all of the above arguments into a list (i.e. a list of lists, or a list of arrays/matrices/vectors), and pass it as the first argument. This is the most convenient way to use this function with the function `tkpar3dsave`.

Interpolation is by cubic spline or linear interpolation in an appropriate coordinate-wise fashion. Extrapolation may oscillate (repeat the sequence forward, backward, forward, etc.), cycle (repeat it forward), be constant (no repetition outside the specified time range), or be natural (linear on an appropriate scale). In the case of cycling, the first and last specified values should be equal, or the last one will be dropped. Natural extrapolation is only supported with spline interpolation.

Value

A function is returned. The function takes one argument, and returns a list of `par3d` settings interpolated to that time.

Note

Prior to `rgl` version 0.95.1476, the `subscene` argument defaulted to the current subscene, and any additional entries would be ignored by `play3d`. The current default value of `par3d("listeners", dev = dev)` means that all subscenes that share mouse responses will also share modifications by this function.

Author(s)

Duncan Murdoch

`play3d` to play the animation.

Examples

```r
f <- par3dinterp( zoom = c(1, 2, 3, 1) )
f(0)
f(1)
f(0.5)
## Not run:
play3d(f)
```

## End(Not run)
par3dinterpControl

Control RGL widget like par3dinterp()

Description
This control works with playwidget to change settings in a WebGL display in the same way as par3dinterp does within R.

Usage
par3dinterpControl(fn, from, to, steps, subscene = NULL, omitConstant = TRUE, ...)

Arguments
- fn: A function returned from par3dinterp.
- from, to, steps: Values where fn should be evaluated.
- subscene: Which subscene's properties should be modified?
- omitConstant: If TRUE, do not set values that are constant across the range.
- ...: Additional parameters which will be passed to propertyControl.

Details
par3dinterpSetter sets parameters corresponding to values produced by the result of par3dinterp.

Value
Returns controller data in a list of class "rglControl".

Author(s)
Duncan Murdoch

Examples
example(plot3d)
M <- r3dDefaults$UserMatrix
fn <- par3dinterp(times = (0:2)*0.75, userMatrix = list(M,
    rotate3d(M, pi/2, 1, 0, 0),
    rotate3d(M, pi/2, 0, 1, 0)),
    scale = c(0.5, 1, 2))
control <- par3dinterpControl(fn, 0, 3, steps = 15)
control
if (interactive() || in_pkgdown_example())
  rglwidget(width = 500, height = 250) %>%
  playwidget(control,
    step = 0.01, loop = TRUE, rate = 0.5)
**pch3d**

Plot symbols similar to base graphics

**Description**

This function plots symbols similarly to what the base graphics function `points` does when `pch` is specified.

**Usage**

```r
pch3d(x, y = NULL, z = NULL, pch = 1,
   bg = material3d("color")[1], cex = 1, radius,
   color = "black", lit = FALSE, ...)
```

**Arguments**

- `x, y, z`: The locations at which to plot in a form suitable for use in `xyz.coords`.
- `pch`: A vector of integers or single characters describing the symbols to plot.
- `bg`: The fill color(s) to use for `pch` from 21 to 25.
- `cex`: A relative size of the symbol to plot.
- `radius`: An absolute size of the symbol to plot in user coordinates.
- `color`: The color(s) to use for symbols.
- `lit`: Whether the object responds to lighting or just shows the displayed color directly.
- `...`: Other material properties.

**Details**

The list of symbols encoded by numerical `pch` values is given in the `points` help page.

**Value**

A vector of object id values is returned invisibly. Separate objects will be drawn for each different combination of `pch` value from 0 to 25, `color` and `bg`, and another holding all the character symbols.

**Note**

This function is not a perfect match to how the `points` function works due to limitations in RGL and OpenGL. In particular:

Symbols with numbers from 1 to 25 are drawn as 3D sprites (see `sprites3d`), so they will resize as the window is zoomed. Letters and numbers from 32 to 255 (which are mapped to letters) are drawn using `text3d`, so they maintain a fixed size.

A calculation somewhat like the one in `plot3d` that sets the size of spheres is used to choose the size of sprites based on `cex` and the current scaling. This will likely need manual tweaking. Use the `radius` argument for a fixed size.
persp3d

No special handling is done for the case of pch = ".". Use points3d for small dots. As of rgl version 0.100.10, background and foreground colors can vary from symbol to symbol.

Author(s)

Duncan Murdoch

See Also

points3d, text3d, plot3d, points.

Examples

open3d()

i <- 0:25; x <- i %% 5; y <- rep(0, 26); z <- i %/% 5
pch3d(x, y, z, pch = i, bg = "gray", color = rainbow(26))
text3d(x, y, z + 0.3, i)
pch3d(x + 5, y, z, pch = i+65)
text3d(x + 5, y, z + 0.3, i+65)

Description

This function draws plots of surfaces in 3-space. persp3d is a generic function.

Usage

persp3d(x, ...)

## Default S3 method:
persp3d(x = seq(0, 1, len = nrow(z)), y = seq(0, 1, len = ncol(z)), z,
xlim = NULL, ylim = NULL, zlim = NULL,
xlab = NULL, ylab = NULL, zlab = NULL, add = FALSE, aspect = !add,
forceClipregion = FALSE, ...)

Arguments

x, y, z points to plot on surface. See Details below.
xlim, ylim, zlim x-, y- and z-limits. If present, the plot is clipped to this region.
xlab, ylab, zlab titles for the axes. N.B. These must be character strings; expressions are not accepted. Numbers will be coerced to character strings.
add whether to add the points to an existing plot.
aspect either a logical indicating whether to adjust the aspect ratio, or a new ratio.
forceClipregion
force a clipping region to be used, whether or not limits are given.

additional material parameters to be passed to surface3d and decorate3d.

Details

The default method plots a surface defined as a grid of \((x, y, z)\) locations in space. The grid may be specified in several ways:

- As with persp, \(x\) and \(y\) may be given as vectors in ascending order, with \(z\) given as a matrix. There should be one \(x\) value for each row of \(z\) and one \(y\) value for each column. The surface drawn will have \(x\) constant across rows and \(y\) constant across columns. This is the most convenient format when \(z\) is a function of \(x\) and \(y\) which are measured on a regular grid.
- \(x\) and \(y\) may also be given as matrices, in which case they should have the same dimensions as \(z\). The surface will combine corresponding points in each matrix into locations \((x, y, z)\) and draw the surface through those. This allows general surfaces to be drawn, as in the example of a spherical Earth shown below.
- If \(x\) is a list, its components \(x\$x\), \(x\$y\) and \(x\$z\) are used for \(x\), \(y\) and \(z\) respectively, though an explicitly specified \(z\) value will have priority.

One difference from persp is that colors are specified on each vertex, rather than on each facet of the surface. To emulate the persp color handling, you need to do the following. First, convert the color vector to an \((nx - 1)\) by \((ny - 1)\) matrix; then add an extra row before row 1, and an extra column after the last column, to convert it to \(nx\) by \(ny\). (These extra colors will not be used). For example, \(col <- rbind(1, cbind(matrix(col, nx - 1, ny - 1), 1))\). Finally, call persp3d with material property \(\text{smooth} = \text{FALSE}\).

See the “Clipping” section in plot3d for more details on \(\text{xlim}, \text{ylim}, \text{zlim}\) and \text{forceClipregion}.

Value

This function is called for the side effect of drawing the plot. A vector of shape IDs is returned invisibly.

Author(s)

Duncan Murdoch

See Also

plot3d, persp. There is a persp3d.function method for drawing functions, and persp3d.deldir can be used to draw surfaces defined by an irregular collection of points. A formula method persp3d.formula draws surfaces using this method.

The surface3d function is used to draw the surface without the axes etc.

Examples

```r
# (1) The Obligatory Mathematical surface.
#     Rotated sinc function.
```
```r
x <- seq(-10, 10, length = 20)
y <- x
f <- function(x, y) { r <- sqrt(x^2 + y^2); 10 * sin(r)/r }
z <- outer(x, y, f)
z[is.na(z)] <- 1
open3d()

# Draw the surface twice: the first draws the solid part,
# the second draws the grid. Offset the first so it doesn't
# obscure the lines.
persp3d(x, y, z, aspect = c(1, 1, 0.5), col = "lightblue",
       xlab = "X", ylab = "Y", zlab = "Sinc( r )",
       polygon_offset = 1)
persp3d(x, y, z, front = "lines", back = "lines",
       lit = FALSE, add = TRUE)
highlevel()  # trigger the plot

# (2) Add to existing persp plot:
xE <- c(-10, 10); xy <- expand.grid(xE, xE)

# This looks much better, but is slow because the texture is very big
persp3d(x, y, z, col = "white",
    texture = system.file("textures/world.png", package = "rgl"),
    specular = "black", axes = FALSE, box = FALSE, xlab = "", ylab = "", zlab = "",
    normal.x = x, normal.y = y, normal.z = z)

## End(Not run)

persp3d.deldir  

Plot a Delaunay triangulation

Description

The deldir() function in the deldir package computes a Delaunay triangulation of a set of points. These functions display it as a surface.

Usage

## S3 method for class 'deldir'
plot3d(x, ...)
## S3 method for class 'deldir'
persp3d(x, ..., add = FALSE)
## S3 method for class 'deldir'
as.mesh3d(x, col = "gray", coords = c("x", "y", "z"),
    smooth = TRUE, normals = NULL, texcoords = NULL, ...)

Arguments

x  
A "deldir" object, produced by the deldir() function. It must contain z values.

add  
Whether to add surface to existing plot (add = TRUE) or create a new plot (add = FALSE, the default).

col  
Colors to apply to each vertex in the triangulation. Will be recycled as needed.

coords  
See Details below.

smooth  
Whether to average normals at vertices for a smooth appearance.

normals  
User-specified normals at each vertex. Requires smooth = FALSE.

texcoords  
Texture coordinates at each vertex.

...  
See Details below.
Details

These functions construct a mesh3d object corresponding to the triangulation in x. The plot3d and persp3d methods plot it.

The coords parameter allows surfaces to be plotted over any coordinate plane. It should be a permutation of the column names c("x","y","z") from the "deldir" object. The first will be used as the x coordinate, the second as the y coordinate, and the third as the z coordinate.

The ... parameters in plot3d.deldir are passed to persp3d.deldir; in persp3d.deldir they are passed to both as.mesh3d.deldir and persp3d.mesh3d; in as.mesh3d.deldir they are used as material parameters in a tmesh3d call.

Examples

```r
x <- rnorm(200, sd = 5)
y <- rnorm(200, sd = 5)
r <- sqrt(x^2 + y^2)
z <- 10 * sin(r)/r
col <- cm.colors(20)[1 + round(19*(z - min(z))/diff(range(z)))]
save <- options(rgl.meshColorWarning = FALSE)
# This code is awkward: to work with demo(rglExamples),
# we need auto-printing of the plots. This means we
# have to repeat the test for deldir.

haveDeldir <- checkDeldir()

if (haveDeldir) {
  dxyz <- deldir::deldir(x, y, z = z, suppressMsge = TRUE)
persp3d(dxyz, col = col)
}
if (haveDeldir) {
  open3d()
  # Do it without smoothing and with a different orientation.
persp3d(dxyz, col = col, coords = c("z", "x", "y"), smooth = FALSE)
}
options(save)
```

---

**persp3d.function**  
*Plot a function of two variables*

---

**Description**

Plot a function $z(x,y)$ or a parametric function $(x(s,t),y(s,t),z(s,t))$.  

## S3 method for class 'function'

```r
persp3d(f,
    xlim = c(0, 1), ylim = c(0, 1),
    slim = NULL, tlim = NULL,
    n = 101,
    xvals = seq.int(min(xlim), max(xlim), length.out = n[1]),
    yvals = seq.int(min(ylim), max(ylim), length.out = n[2]),
    svals = seq.int(min(slim), max(slim), length.out = n[1]),
    tvals = seq.int(min(tlim), max(tlim), length.out = n[2]),
    xlab, ylab, zlab,
    col = "gray", otherargs = list(),
    normal = NULL, texcoords = NULL, ...)
```

## S3 method for class 'function'

```r
plot3d(x, ...)```

### Arguments

- **x**
  A function of two arguments. See the details below.

- **xlim, ylim**
  By default, the range of x and y values. For a parametric surface, if these are not missing, they are used as limits on the displayed x and y values.

- **slim, tlim**
  If not NULL, these give the range of s and t in the parametric specification of the surface. If only one is given, the other defaults to c(0, 1).

- **n**
  A one or two element vector giving the number of steps in the x and y (or s and t) grid.

- **xvals, yvals**
  The values at which to evaluate x and y. Ignored for a parametric surface. If used, xlim and/or ylim are ignored.

- **svals, tvals**
  The values at which to evaluate s and t for a parametric surface. Only used if slim or tlim is not NULL. As with xvals and yvals, these override the corresponding slim or tlim specification.

- **xlab, ylab, zlab**
  The axis labels. See the details below for the defaults.

- **col**
  The color to use for the plot. See the details below.

- **otherargs**
  Additional arguments to pass to the function.

- **normal, texcoords**
  Functions to set surface normals or texture coordinates. See the details below.

- **...**
  Additional arguments to pass to `persp3d`.

### Details

The "function" method for `plot3d` simply passes all arguments to `persp3d`. Thus this description applies to both.

The first argument `x` is required to be a function. It is named `x` only because of the requirements of the S3 system; in the remainder of this help page, we will assume that the assignment `f <- x` has been made, and will refer to the function `f()`. 
persp3d.function evaluates \( f() \) on a two-dimensional grid of values, and displays the resulting surface. The values on the grid will be passed in as vectors in the first two arguments to the function, so \( f() \) needs to be vectorized. Other optional arguments to \( f() \) can be specified in the `otherargs` list.

In the default form where `xlim` and `ylim` are both `NULL`, it is assumed that \( f(x, y) \) returns heights, which will be plotted in the \( z \) coordinate. The default axis labels will be taken from the argument names to \( f() \) and the expression passed as argument \( x \) to this function.

If `xlim` or `ylim` is specified, a parametric surface is plotted. The function \( f(s, t) \) must return a 3-column matrix, giving \( x, y \) and \( z \) coordinates of points on the surface. The default axis labels will be the column names if those are present. In this case `xlim`, `ylim` and `zlim` are used to define a clipping region only if specified; the defaults are ignored.

The color of the surface may be specified as the name of a color, or a vector or matrix of color names. In this case the colors will be recycled across the points on the grid of values.

Alternatively, a function may be given: it should be a function like `rainbow` that takes an integer argument and returns a vector of colors. In this case the colors are mapped to \( z \) values.

The `normal` argument allows specification of a function to compute normal vectors to the surface. This function is passed the same arguments as \( f() \) (including `otherargs` if present), and should produce a 3-column matrix containing the \( x, y \) and \( z \) coordinates of the normals.

The `texcoords` argument is a function similar to `normal`, but it produces a 2-column matrix containing texture coordinates.

Both `normal` and `texcoords` may also contain matrices, with 3 and 2 columns respectively, and rows corresponding to the points that were passed to \( f() \).

**Value**

This function constructs a call to `persp3d` and returns the value from that function.

**Author(s)**

Duncan Murdoch

**See Also**

The `curve` function in base graphics does something similar for functions of one variable. See the example below for space curves.

**Examples**

```r
# (1) The Obligatory Mathematical surface.
#     Rotated sinc function, with colors

f <- function(x, y) {
  r <- sqrt(x^2 + y^2)
  ifelse(r == 0, 10, 10 * sin(r)/r)
}
open3d()
plot3d(f, col = colorRampPalette(c("blue", "white", "red")), xlab = "X", ylab = "Y", zlab = "Sinc( r )",
```

```r
xlim = c(-10, 10), ylim = c(-10, 10),
aspect = c(1, 1, 0.5))
# (2) A cylindrical plot

f <- function(s, t) {
  r <- 1 + exp(-pmin((s - t)^2,
    (s - t - 1)^2,
    (s - t + 1)^2 )/0.01 )
  cbind(r*cos(t*2*pi), r*sin(t*2*pi), s)
}
open3d()
plot3d(f, slim = c(0, 1), tlim = c(0, 1), col = "red", alpha = 0.8)
# Add a curve to the plot, fixing s at 0.5.
plot3d(f(0.5, seq.int(0, 1, length.out = 100)), type = "l", add = TRUE,
  lwd = 3, depth_test = "lequal")
```

---

**Description**

The `tri.mesh()` functions in the **interp** and **tripack** packages compute a Delaunay triangulation of a set of points. These functions display it as a surface.

**Usage**

```r
## S3 method for class 'triSht'
plot3d(x, z, ...)
## S3 method for class 'triSht'
persp3d(x, z, ..., add = FALSE)
## S3 method for class 'triSht'
as.mesh3d(x, z, col = "gray", coords = c("x", "y", "z"),
  smooth = TRUE, normals = NULL, texcoords = NULL, ...)
## S3 method for class 'tri'
plot3d(x, z, ...)
## S3 method for class 'tri'
persp3d(x, z, ..., add = FALSE)
## S3 method for class 'tri'
as.mesh3d(x, z, col = "gray", coords = c("x", "y", "z"),
  smooth = TRUE, normals = NULL, texcoords = NULL, ...)
```

**Arguments**

- `x` A "triSht" or "tri" object, produced by the `tri.mesh()` function in the **interp** or **tripack** packages respectively.
z

z coordinate values corresponding to each of the nodes in x.

add

Whether to add surface to existing plot (add = TRUE) or create a new plot (add = FALSE, the default).

col

Colors to apply to each vertex in the triangulation. Will be recycled as needed.

coords

See Details below.

smooth

Whether to average normals at vertices for a smooth appearance.

normals

User-specified normals at each vertex. Requires smooth = FALSE.

texcoords

Texture coordinates at each vertex.

... See Details below.

Details

These functions construct a mesh3d object corresponding to the triangulation in x. The plot3d and persp3d methods plot it.

The coords parameter allows surfaces to be plotted over any coordinate plane. It should be a permutation of the column names c("x", "y", "z"). The first will be used as the x coordinate, the second as the y coordinate, and the third as the z coordinate.

The ... parameters in plot3d.triSht and plot3d.tri are passed to persp3d; in persp3d.triSht and persp3d.tri they are passed to both as.mesh3d and persp3d.mesh3d; in as.mesh3d.triSht and as.mesh3d.tri they are used as material parameters in a tmesh3d call.

"tri" objects may contain constraints. These appear internally as extra nodes, representing either the inside or outside of boundaries on the region being triangulated. Each of these nodes should also have a z value, but triangles corresponding entirely to constraint nodes will not be drawn. In this way complex, non-convex regions can be triangulated. See the second example below.

Note

If there are duplicate points, the tri.mesh() functions will optionally delete some of them. If you choose this option, the z values must correspond to the nodes after deletion, not before.

Examples

```r
x <- rnorm(200, sd = 5)
y <- rnorm(200, sd = 5)
r <- sqrt(x^2 + y^2)
z <- 10 * sin(r)/r
col <- cm.colors(20)[1 + round(19*(z - min(z))/diff(range(z)))]
save <- NULL
if ((haveinterp <- requireNamespace("interp", quietly = TRUE))) {
  save <- options(rgl.meshColorWarning = FALSE)
  dxy <- interp::tri.mesh(x, y)
  open3d()
persp3d(dxy, z, col = col, meshColor = "vertices")
}
if (haveinterp) {
  open3d()
  # Do it without smoothing and with a different orientation.
}
planes3d

Description

planes3d adds mathematical planes to a scene. Their intersection with the current bounding box will be drawn. clipplanes3d adds clipping planes to a scene.

Usage

planes3d(a, b = NULL, c = NULL, d = 0, ...) clipplanes3d(a, b = NULL, c = NULL, d = 0)

Arguments

a, b, c Coordinates of the normal to the plane. Any reasonable way of defining the coordinates is acceptable. See the function xyz.coords for details.
d Coordinates of the "offset". See the details.
... Material properties. See rgl.material for details.

Details

planes3d draws planes using the parametrization $ax + by + cz + d = 0$. Multiple planes may be specified by giving multiple values for any of a, b, c, d; the other values will be recycled as necessary.

clipplanes3d defines clipping planes using the same equations. Clipping planes suppress the display of other objects (or parts of them) in the subscene, based on their coordinates. Points (or
parts of lines or surfaces) where the coordinates $x,y,z$ satisfy $ax + by + cz + d < 0$ will be suppressed.

The number of clipping planes supported by the OpenGL driver is implementation dependent; use \texttt{par3d("maxClipPlanes")} to find the limit.

\textbf{Value}

A shape ID of the planes or clipplanes object is returned invisibly.

\textbf{See Also}

\texttt{abclines3d} for mathematical lines.
\texttt{triangles3d} or the corresponding functions for quadrilaterals may be used to draw sections of planes that do not adapt to the bounding box.

The example in \texttt{subscene3d} shows how to combine clipping planes to suppress complex shapes.

\textbf{Examples}

```
# Show regression plane with z as dependent variable

open3d()
x <- rnorm(100)
y <- rnorm(100)
z <- 0.2*x - 0.3*y + rnorm(100, sd = 0.3)
fit <- lm(z ~ x + y)
plot3d(x, y, z, type = "s", col = "red", size = 1)

coefs <- coef(fit)
a <- coefs["x"]
b <- coefs["y"]
c <- -1
d <- coefs["(Intercept)"]
planes3d(a, b, c, d, alpha = 0.5)

open3d()
ids <- plot3d(x, y, z, type = "s", col = "red", size = 1, forceClipregion = TRUE)
oldid <- useSubscene3d(ids["clipregion")]
clipplanes3d(a, b, c, d)
useSubscene3d(oldid)
```

\textbf{Description}

\texttt{play3d} calls a function repeatedly, passing it the elapsed time in seconds, and using the result of the function to reset the viewpoint. \texttt{movie3d} does the same, but records each frame to a file to make a movie.
Usage

\begin{verbatim}
play3d(f, duration = Inf, dev = cur3d(), ..., startTime = 0)
movie3d(f, duration, dev = cur3d(), ..., fps = 10,
       movie = "movie", frames = movie, dir = tempdir(),
       convert = NULL, clean = TRUE, verbose = TRUE,
       top = !rgl.useNULL(), type = "gif", startTime = 0,
       webshot = TRUE)
\end{verbatim}

Arguments

\begin{itemize}
  \item \texttt{f}  A function returning a list that may be passed to \texttt{par3d}
  \item \texttt{duration}  The duration of the animation
  \item \texttt{dev}  Which RGL device to select
  \item ...  Additional parameters to pass to \texttt{f}.
  \item \texttt{startTime}  Initial time at which to start the animation
  \item \texttt{fps}  Number of frames per second
  \item \texttt{movie}  The base of the output filename, not including .gif
  \item \texttt{frames}  The base of the name for each frame
  \item \texttt{dir}  A directory in which to create temporary files for each frame of the movie
  \item \texttt{convert}  How to convert to a GIF movie; see Details
  \item \texttt{clean}  If \texttt{convert} is NULL or TRUE, whether to delete the individual frames
  \item \texttt{verbose}  Whether to report the convert command and the output filename
  \item \texttt{top}  Whether to call \texttt{rgl.bringtotop} before each frame
  \item \texttt{type}  What type of movie to create. See Details.
  \item \texttt{webshot}  Whether to use the \texttt{webshot2} package for snapshots of frames. See \texttt{snapshot3d}.
\end{itemize}

Details

The function \texttt{f} will be called in a loop with the first argument being the \texttt{startTime} plus the time in seconds since the start (where the start is measured after all arguments have been evaluated).

\texttt{play3d} is likely to place a high load on the CPU; if this is a problem, calls to \texttt{Sys.sleep} should be made within the function to release time to other processes.

\texttt{play3d} will run for the specified \texttt{duration} (in seconds), but can be interrupted by pressing ESC while the RGL window has the focus.

\texttt{movie3d} saves each frame to disk in a filename of the form ‘framesXXX.png’, where XXX is the frame number, starting from 0. If \texttt{convert} is \texttt{NULL} (the default) and the \texttt{magick} package is installed, it will be used to convert the frames to a GIF movie (or other format if supported). If \texttt{magick} is not installed or \texttt{convert} is \texttt{TRUE}, \texttt{movie3d} will attempt to use the external ImageMagick program to convert the frames to a movie. The newer \texttt{magick} executable is tried first, then \texttt{convert} if that fails. The \texttt{type} argument will be passed to \texttt{ImageMagick} to use as a file extension to choose the file type.
Finally, convert can be a template for a command to execute in the standard shell (wildcards are allowed). The template is converted to a command using
\texttt{sprintf(convert, fps, frames, movie, type, duration, dir)}

For example, convert = \texttt{TRUE} uses the template "magick \texttt{-delay 1x%d %s*.png %s.%s}". All work is done in the directory dir, so paths should not be needed in the command. (Note that \texttt{sprintf} does not require all arguments to be used, and supports formats that use them in an arbitrary order.)

The \texttt{top = TRUE} default is designed to work around an OpenGL limitation: in some implementations, \texttt{rgl.snapshot} will fail if the window is not topmost.

As of \texttt{rgl} version 0.94, the dev argument is not needed: the function \( f \) can specify its device, as \texttt{spin3d} does, for example. However, if dev is specified, it will be selected as the current device as each update is played.

As of \texttt{rgl} version 0.95.1476, \( f \) can include multiple values in a "subscene" component, and \texttt{par3d()} will be called for each of them.

\textbf{Value}

\texttt{play3d} is called for the side effect of its repeated calls to \( f \). It returns \texttt{NULL} invisibly.

\texttt{movie3d} is also normally called for the side effect of producing the output movie. It invisibly returns

\textbf{Author(s)}

Duncan Murdoch, based on code by Michael Friendly

\textbf{See Also}

\texttt{spin3d} and \texttt{par3dinterp} return functions suitable to use as \( f \). See \texttt{demo(flag)} for an example that modifies the scene in \( f \).

\textbf{Examples}

\begin{verbatim}
open3d()
plot3d( cube3d(col = "green") )
M <- par3d("userMatrix")
if (!rgl.useNULL())
  play3d( par3dinterp(time = (0:2)*0.5, userMatrix = list(M,
    rotate3d(M, pi/2, 1, 0, 0),
    rotate3d(M, pi/2, 0, 1, 0) ) ),
    duration = 2 )
## Not run:
movie3d( spin3d(), duration = 5 )
## End(Not run)
\end{verbatim}
playwidget

Add a widget to play animations

Description

This is a widget that can be put in a web page to allow animations with or without Shiny.

Usage

playwidget(sceneId, controls, 
  start = 0, stop = Inf, interval = 0.05, rate = 1, 
  components = c("Reverse", "Play", "Slower", "Faster", 
                   "Reset", "Slider", "Label"), 
  loop = TRUE, 
  step = 1, labels = NULL, 
  precision = 3, 
  elementId = NULL, respondTo = NULL, 
  reinit = NULL, 
  buttonLabels = components, pause = "Pause", 
  height = 40, 
  ...)

Arguments

sceneId The HTML id of the RGL scene being controlled, or an object. See the Details below.
controls A single "rglControl" object, e.g. propertyControl, or a list of several.
start, stop The starting and stopping values of the animation. If labels is supplied stop 
will default to step through the labels.
interval The requested interval (in seconds) between updates. Updates may occur at 
longer intervals.
rate The number of units of “nominal” time per real world second.
components Which components should be displayed? See Details below.
loop When the player reaches the end of the interval, should it loop back to the be-
ginning?
step Step size in the slider.
labels Optional labels to use, corresponding to slider steps. Set to NULL for auto-
generated labels.
precision If labels=NULL, the precision to use when displaying timer values.
elementId The HTML id of the generated widget, containing buttons, slider, etc.
respondTo The HTML ID of a Shiny input control (e.g. a sliderInput control) to respond to.
reinit

A vector of ids that will need re-initialization before being drawn again.

buttonLabels, pause

These are the labels that will be shown on the buttons if they are displayed.
pause will be shown on the "Play" button while playing.

height

The height of the widget in pixels. In a pipe, this is a relative height.

... Additional arguments to pass to htmlwidgets::createWidget.

Details

The components are buttons to control the animation, a slider for manual control, and a label to show the current value. They will be displayed in the order given in components. Not all need be included.

The buttons have the following behaviour:

Reverse Reverse the direction.
Play Play the animation.
Slower Decrease the playing speed.
Faster Increase the playing speed.
Reset Stop the animation and reset to the start value.

If respondTo is used, no components are shown, as it is assumed Shiny (or whatever control is being referenced) will provide the UI components.

The sceneId component can be another playwidget, a rglwidget result, or a result of htmltools::tags or htmltools::tagList. This allows you to use a magrittr-style “pipe” command to join an rglwidget with one or more playwidgets. If a playwidget comes first, sceneId should be set to NA. If the rglwidget does not come first, previous values should be piped into its controllers argument. Other HTML code (including other widgets) can be used in the chain if wrapped in htmltools::tagList.

Value

A widget suitable for use in an Rmarkdown-generated web page, or elsewhere.

Appearance

The appearance of the controls is set by the stylesheet in system.file("htmlwidgets/lib/rglClass/rgl.css").

The overall widget is of class rglPlayer, with id set according to elementId.

The buttons are of HTML class rgl-button, the slider is of class rgl-slider, and the label is of class rgl-label. Each element has an id prefixed by the widget id, e.g. elementId-button-Reverse, elementId-slider, etc. (where elementId should be replaced by the actual id).

The reinit parameter handles the case where an object needs re-initialization after each change. For example, plane objects may need this if their intersection with the bounding box changes shape. Note that re-initialization is generally incompatible with the vertexControl as it modifies values which are set during initialization.
Author(s)
Duncan Murdoch

See Also
subsetControl, propertyControl, ageControl and vertexControl are possible controls to use.
toggleWidget is a wrapper for playwidget and subsetControl to insert a single button to toggle some elements in a display.

Examples

```r
saveopts <- options(rgl.useNULL = TRUE)

objid <- plot3d(1:10, 1:10, rnorm(10), col=c("red", "red"), type = "s")["data"]

control <- ageControl(value=0,
births=1:10,
ages = c(-5,0,5),
colors = c("green", "yellow", "red"),
objids = objid)

# This example uses explicit names
rglwidget(elementId = "theplot", controllers = "theplayer",
  height = 300, width = 300)
playwidget("theplot", control, start = -5, stop = 5,
  rate = 3, elementId = "theplayer",
  components = c("Play", "Slider"))

# This example uses pipes, and can skip the names
widget <- rglwidget(height = 300, width = 300) %>%
  playwidget(control, start = -5, stop = 5,
     rate = 3, components = c("Play", "Slider"))
if (interactive() || in_pkgdown_example())
  widget

options(saveopts)
```

Description

Draws a 3D scatterplot.
Usage

plot3d(x, ...)  
## Default S3 method:  
plot3d(x, y, z,  
xlab, ylab, zlab, type = "p",  
col, size, lwd, radius,  
add = FALSE, aspect = !add,  
xlim = NULL, ylim = NULL, zlim = NULL,  
forceClipregion = FALSE,  
decorate = !add, ...)  
## S3 method for class 'mesh3d'  
plot3d(x, xlab = "x", ylab = "y", zlab = "z", type = c("shade", "wire", "dots"),  
add = FALSE, aspect = !add, ...)

Arguments

x, y, z  
>vectors of points to be plotted. Any reasonable way of defining the coordinates is acceptable. See the function xyz.coords for details.

xlab, ylab, zlab  
>labels for the coordinates.

type  
>For the default method, a single character indicating the type of item to plot. Supported types are: 'p' for points, 's' for spheres, 'l' for lines, 'h' for line segments from \( z = 0 \), and 'n' for nothing. For the mesh3d method, one of 'shade', 'wire', or 'dots'. Partial matching is used.

col  
>the color to be used for plotted items.

size  
>the size for plotted points.

lwd  
>the line width for plotted items.

radius  
>the radius of spheres: see Details below.

add  
>whether to add the points to an existing plot.

aspect  
>either a logical indicating whether to adjust the aspect ratio, or a new ratio.

xlim, ylim, zlim  
>If not NULL, set clipping limits for the plot.

forceClipregion  
>Force a clipping region to be used, whether or not limits are given.

decorate  
>Whether to add bounding axes and other decorations.

...  
>additional parameters which will be passed to par3d, material3d or decorate3d.

Details

plot3d is a partial 3D analogue of plot.default.

Missing values in the data are skipped, as in standard graphics.

If aspect is TRUE, aspect ratios of c(1, 1, 1) are passed to aspect3d. If FALSE, no aspect adjustment is done. In other cases, the value is passed to aspect3d.
With `type = "s"`, spheres are drawn centered at the specified locations. The radius may be controlled by `size` (specifying the size relative to the plot display, with the default `size = 3` giving a radius about 1/20 of the plot region) or `radius` (specifying it on the data scale if an isometric aspect ratio is chosen, or on an average scale if not).

### Value

`plot3d` is called for the side effect of drawing the plot; a vector of object IDs is returned.

### Clipping

If any of `xlim`, `ylim` or `zlim` are specified, they should be length two vectors giving lower and upper clipping limits for the corresponding coordinate. NA limits will be ignored.

If any clipping limits are given, then the data will be plotted in a newly created subscene within the current one; otherwise plotting will take place directly in the current subscene. This subscene is named "clipregion" in the results. This may affect the appearance of transparent objects if some are drawn in the `plot3d` call and others after, as RGL will not attempt to depth-sort objects if they are in different subscenes. It is best to draw all overlapping transparent objects in the same subscene. See the example in `planes3d`. It will also affect the use of `clipplanes3d`; clipping planes need to be in the same subscene as the objects being clipped.

Use `forceClipregion = TRUE` to force creation of this subscene even without specifying limits.

### Author(s)

Duncan Murdoch

### See Also

`plot.default`, `open3d`, `par3d`. There are `plot3d.function` and `plot3d.deldir` methods for plotting surfaces.

### Examples

```r
open3d()
x <- sort(rnorm(1000))
y <- rnorm(1000)
z <- rnorm(1000) + atan2(x, y)
plot3d(x, y, z, col = rainbow(1000))
```
Usage

```r
## S3 method for class \'formula\'
plot3d(x, data = NULL, xlab, ylab, zlab, ...)
## S3 method for class \'formula\'
persp3d(x, data = NULL, xlab, ylab, zlab, ...)
```

Arguments

- `x`: A formula like `z ~ x + y`.
- `data`: An optional dataframe or list in which to find the components of the formula.
- `xlab`, `ylab`, `zlab`: Optional axis labels to override the ones automatically obtained from the formula.
- `...`: Additional arguments to pass to the default `plot3d` method, or the `persp3d` method for "deldir" objects.

Details

Only simple formulas (the ones handled by the `xyz.coords` function) are supported: a single variable on the left hand side (which will be plotted on the Z axis), and a sum of two variables on the right hand side (which will be the X and Y axis variables in the plot.)

Value

These functions are called for the side effect of drawing the plots. The `plot3d` method draws a scatterplot. The `persp3d` method draws a surface plot.

Return values are as given by the `plot3d.default` method or the `persp3d.deldir` methods.

Note

The `persp3d` method requires that the suggested package `deldir` is installed.

Duncan Murdoch

Examples

```r
open3d()
mfrow3d(1, 2, sharedMouse = TRUE)
plot3d(mpg ~ wt + qsec, data = mtcars)
if (checkDeldir())
  persp3d(mpg ~ wt + qsec, data = mtcars)
```
plot3d.lm

Method for plotting simple linear fit

Description

This function provides several plots of the result of fitting a two-predictor model.

Usage

```r
## S3 method for class 'lm'
plot3d(x,
       which = 1,
       plane.col = "gray", plane.alpha = 0.5,
       sharedMouse = TRUE,
       use_surface3d,
       do_grid = TRUE,
       grid.col = "black",
       grid.alpha = 1,
       grid.steps = 5,
       sub.steps = 4,
       vars = get_all_vars(terms(x), x$model),
       clip_to_density = 0,
       ...)
```

Arguments

- `x` An object inheriting from class "lm" obtained by fitting a two-predictor model.
- `which` Which plot to show? See Details below.
- `plane.col`, `plane.alpha` These parameters control the colour and transparency of a plane or surface.
- `sharedMouse` If multiple plots are requested, should they share mouse controls, so that they move in sync?
- `use_surface3d` Use the `surface3d` function to plot the surface rather than `planes3d`. This allows curved surfaces to be shown. The default is FALSE if the model looks like a simple 2 parameter linear fit, otherwise TRUE.
- `do_grid` Plot a grid.
- `grid.col`, `grid.alpha`, `grid.steps` Characteristics of the grid.
- `sub.steps` If `use_surface3d` is TRUE, use an internal grid of `grid.steps*sub.steps` to draw the surface. `sub.steps > 1` allows curvature within facets. Similarly, if `do_grid` is TRUE, it allows curvature within grid lines.
- `vars` A dataframe containing the variables to plot in the first three columns, with the response assumed to be in column 1. See the Note below.
clip_to_density
   If positive, the surface, plane or grid will be clipped to a region with sufficient data.

... Other parameters to pass to the default plot3d method, to control the appearance of aspects of the plot other than the plane.

Details

Three plots are possible, depending on the value(s) in which:

1. (default) Show the points and the fitted plane or surface.
2. Show the residuals and the plane at z = 0.
3. Show the predicted values on the fitted plane or surface.

If clip_to_density is positive, then the surface, plane or grid will be clipped to the region where a non-parametric density estimate (using MASS::kde2d), normalized to have a maximum value of 1, is greater than the given value. This will suppress parts of the plot that aren’t supported by the observed data.

Value

Called for the side effect of drawing one or more plots.

Invisibly returns a high-level vector of object ids. Names of object ids have the plot number (in drawing order) appended.

Note

The default value for the vars argument will handle simple linear models with a response and two predictors, and some models with functions of those two predictors. For models that fail (e.g. models using poly), you can include the observed values as in the third example below.

If clip_to_density > 0,

1. The clipping is approximate, so it may not agree perfectly between surfaces, planes and grids.
2. This option requires the suggested packages MASS and akima, and will be ignored with a warning if either is not installed.

Author(s)

Duncan Murdoch

Examples

open3d()
ids <- plot3d(lm(mpg ~ wt + qsec, data = mtcars), which = 1:3)
names(ids)

open3d()
plot3d(lm(mpg ~ wt + I(wt^2) + qsec, data = mtcars))

open3d()
plotmath3d

# Specify vars in the order: response, pred1, pred2.
plot3d(lm(mpg ~ poly(wt, 3) + qsec, data = mtcars),
    vars = mtcars[,c("mpg", "wt", "qsec")])

draw3d()
# Clip parts of the plot with few (wt, qsec) points
plot3d(lm(mpg ~ poly(wt, 3) + qsec, data = mtcars),
    vars = mtcars[,c("mpg", "wt", "qsec")],
    clip_to_density = 0.1)

plotmath3d

Draw text using base graphics math plotting

Description
To plot mathematical text, this function uses base graphics functions to plot it to a `.png` file, then uses that file as a texture in a sprite.

Usage

```r
plotmath3d(x, y = NULL, z = NULL, text, cex = par("cex"),
    adj = 0.5, pos = NULL, offset = 0.5,
    fixedSize = TRUE, startsize = 480, initCex = 5, ...)
```

Arguments

- **x, y, z** coordinates. Any reasonable way of defining the coordinates is acceptable. See the function `xyz.coords` for details.
- **text** A character vector or expression. See `plotmath` for how expressions are interpreted.
- **cex** Character size expansion.
- **adj** one value specifying the horizontal adjustment, or two, specifying horizontal and vertical adjustment respectively, or three, for depth as well.
- **pos, offset** alternate way to specify `adj`; see `text3d`
- **fixedSize** Should the resulting sprite behave like the default ones, and resize with the scene, or like text, and stay at a fixed size?
- **startsize, initCex** These parameters are unlikely to be needed by users. `startsize` is an overestimate of the size (in pixels) of the largest expression. Increase this if large expressions are cut off. `initCex` is the size of text used to form the bitmap. Increase this if letters look too blurry at the desired size.
- **...** Additional arguments to pass to `text` when drawing the text.

Value
Called for the side effect of displaying the sprites. The shape ID of the displayed object is returned.
Note

The `text3d` function passes calls to this function if its `usePlotmath` argument is `TRUE`. The default value is determined by examining its `texts` argument; if it looks like an expression, `plotmath3d` is used.

text3d

Examples

```r
open3d()
# This lets the text resize with the plot
text3d(4, 4, 4, "resizeable text", usePlotmath = TRUE, fixedSize = FALSE)
```

Add primitive shape

Points 3D

Description

Adds a shape node to the current scene.

Usage

```r
points3d(x, y = NULL, z = NULL, ...)
lines3d(x, y = NULL, z = NULL, ...)
segments3d(x, y = NULL, z = NULL, ...)
triangles3d(x, y = NULL, z = NULL, ...)
quads3d(x, y = NULL, z = NULL, ...)
```

Arguments

- **x, y, z**
  - coordinates. Any reasonable way of defining the coordinates is acceptable. See the function `xyz.coords` for details.

- **...**
  - Material properties (see `material3d`). For normals use `normals` and for texture coordinates use `texcoords`; see `rgl.primitive` for details.
points3d

Details

The functions points3d, lines3d, segments3d, triangles3d and quads3d add points, joined lines, line segments, filled triangles or quadrilaterals to the plots. They correspond to the OpenGL types GL_POINTS, GL_LINE_STRIP, GL_LINES, GL_TRIANGLES and GL_QUADS respectively.

Points are taken in pairs by segments3d, triplets as the vertices of the triangles, and quadruplets for the quadrilaterals. Colors are applied vertex by vertex; if different at each end of a line segment, or each vertex of a polygon, the colors are blended over the extent of the object. Polygons must be non-degenerate and quadrilaterals must be entirely in one plane and convex, or the results are undefined.

These functions call the lower level functions rgl.points, rgl.linestrips.

The appearance of the new objects are defined by the material properties. See rgl.material for details.

The two principal differences between the rgl.* functions and the *3d functions are that the former set all unspecified material properties to defaults, whereas the latter use current values as defaults; the former make persistent changes to material properties with each call, whereas the latter make temporary changes only for the duration of the call.

Value

Each function returns the integer object ID of the shape that was added to the scene. These can be passed to pop3d to remove the object from the scene.

Ming Chen and Duncan Murdoch

Examples

# Show 12 random vertices in various ways.

M <- matrix(rnorm(36), 3, 12, dimnames = list(c('x', 'y', 'z'), rep(LETTERS[1:4], 3)))

# Force 4-tuples to be convex in planes so that quads3d works.

for (i in c(1, 5, 9)) {
  quad <- as.data.frame(M[, i + 0:3])
  coeffs <- runif(2, 0, 3)
  if (mean(coeffs) < 1) coeffs <- coeffs + 1 - mean(coeffs)
  quad$C <- with(quad, coeffs[1]*(B - A) + coeffs[2]*(D - A) + A)
  M[, i + 0:3] <- as.matrix(quad)
}

open3d()

# Rows of M are x, y, z coords; transpose to plot

M <- t(M)
shift <- matrix(c(-3, 3, 0), 12, 3, byrow = TRUE)
```r
polygon3d(M)
lines3d(M + shift)
segments3d(M + 2*shift)
triangles3d(M + 3*shift, col = 'red')
quads3d(M + 4*shift, col = 'green')
text3d(M + 5*shift, texts = 1:12)

# Add labels
shift <- outer(0:5, shift[1, ])
shift[, 1] <- shift[, 1] + 3
text3d(shift,
       texts = c('points3d', 'lines3d', 'segments3d',
                  'triangles3d', 'quads3d', 'text3d'),
       adj = 0)
rgl.bringtotop()
```

---

**polygon3d**

*Draw a polygon in three dimensions*

**Description**

This function takes a description of a flat polygon in x, y and z coordinates, and draws it in three dimensions.

**Usage**

```r
polygon3d(x, y = NULL, z = NULL, fill = TRUE, plot = TRUE,
           coords = 1:2, random = TRUE, ...)
```

**Arguments**

- `x, y, z`  
  Vertices of the polygon in a form accepted by `xyz.coords`.
- `fill`  
  logical; should the polygon be filled?
- `plot`  
  logical; should the polygon be displayed?
- `coords`  
  Which two coordinates (x = 1, y = 2, z = 3) describe the polygon.
- `random`  
  Should a random triangulation be used?
- `...`  
  Other parameters to pass to `lines3d` or `shade3d` if `plot = TRUE`.

**Details**

The function triangulates the two dimensional polygon described by `coords`, then applies the triangulation to all three coordinates. No check is made that the polygon is actually all in one plane, but the results may be somewhat unpredictable (especially if `random = TRUE`) if it is not. Polygons need not be simple; use `NA` to indicate separate closed pieces. For `fill = FALSE` there are no other restrictions on the pieces, but for `fill = TRUE` the resulting two-dimensional polygon needs to be one that `triangulate` can handle.
propertyControl

Controls to use with playwidget()

Description

These are setter functions to produce actions in a Shiny app, or in an animation.

Value

If `plot = TRUE`, the id number of the lines (for `fill = FALSE`) or triangles (for `fill = TRUE`) that have been plotted.

If `plot = FALSE`, then for `fill = FALSE`, a vector of indices into the XYZ matrix that could be used to draw the polygon. For `fill = TRUE`, a triangular mesh object representing the triangulation.

Author(s)

Duncan Murdoch

See Also

eextrude3d for a solid extrusion of a polygon, triangulate for the triangulation.

Examples

```r
theta <- seq(0, 4*pi, len = 50)
r <- theta + 1
r <- c(r[-50], rev(theta*0.8) + 1)
theta <- c(theta[-50], rev(theta))
x <- r*cos(theta)
y <- r*sin(theta)
open3d()
plot(x, y, type = "n")
polygon(x, y)
polygon3d(x, y, x + y, col = "blue")
```

```
subsetControl(value = 1, subsets, subscenes = NULL,
               fullset = Reduce(union, subsets),
               accumulate = FALSE)
propertyControl(value = 0, entries, properties,
                 objids = tagged3d(tags), tags, values = NULL,
                 param = seq_len(NROW(values)) - 1, interp = TRUE)
```
Arguments

value
The value to use for input (typically `input$value` in a Shiny app.)

subsets
A list of vectors of object identifiers; the value will choose among them.

fullset
Objects in the subscene which are not in `fullset` will not be touched.

subscenes
The subscenes to be controlled. If `NULL`, the root subscene.

accumulate
If `TRUE`, the subsets will accumulate (by union) as the value increases.

entries, properties, objids
Which properties to set.

tags
Select objects with matching tags. Ignored if `objids` is specified.

values
Values to set.

param
Parameter values corresponding to the rows of `value`

interp
Whether to use linear interpolation between `param` values

Details

`subsetControl` produces data for `playwidget` to display subsets of the object in one or more subscenes. This code will not touch objects in the subscenes if they are not in `fullset`. `fullset` defaults to the union of all the object ids mentioned in `subsets`, so by default if an id is not mentioned in one of the subsets, it will not be controlled by the slider. If `value` is specified in R code, it will be a 1-based index into the `subsets` list; when specified internally in Javascript, 0-based indexing into the corresponding array will be used.

`propertyControl` sets individual properties. Here the row of `values` is determined by the position of `value` in `param`.

Value

These functions return controller data in a list of class "rglControl".

Author(s)

Duncan Murdoch

`subsetSetter` for a way to embed a pure Javascript control, and `playwidget` for a way to use these in animations (including Shiny), `rglShared` for linking using the `crosstalk` package.
propertySetter

Obsolete functions to write HTML/Javascript code to control a WebGL display

Description

These functions write out HTML code to control WebGL displays based using the obsolete writeWebGL. Use playwidget and related functions instead.

Usage

```
propertySlider(setter = propertySetter,
               minS = NULL, maxS = NULL, step = 1, init = NULL,
               labels,
               id = basename(tempfile("input")), name = id,
               outputid = paste0(id, "text"),
               index = NULL,
               ...)

propertySetter(values = NULL, entries, properties, objids, prefixes = "",
                param = seq_len(NROW(values)), interp = TRUE, digits = 7)

par3dinterpSetter(fn, from, to, steps, subscene, omitConstant = TRUE,
                   rename = character(), ...)

matrixSetter(fns, from, to, steps, subscene = currentSubscene3d(),
             matrix = "userMatrix", omitConstant = TRUE, prefix = "", ...)

vertexSetter(values, vertices = 1, attributes, objid, prefix = "",
              param = seq_len(NROW(values)), interp = TRUE,
              digits = 7)
```

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>setter</td>
<td>A function to write Javascript code, or its output, or a list containing several of these.</td>
</tr>
<tr>
<td>minS, maxS, step, init</td>
<td>Slider values to be displayed. Reasonable defaults are used if missing.</td>
</tr>
<tr>
<td>labels</td>
<td>Labels to display for each slider value. The defaults are calculated using internal variables. If NULL, no labels will be shown.</td>
</tr>
<tr>
<td>id</td>
<td>The id of the input control that will be generated.</td>
</tr>
<tr>
<td>name</td>
<td>The name of the input control that will be generated.</td>
</tr>
<tr>
<td>outputid</td>
<td>The id of the output control that will display the slider value, or NULL for none.</td>
</tr>
<tr>
<td>index</td>
<td>The 1-based index of this slider: it controls the corresponding entry in an indexed setter such as matrixSetter.</td>
</tr>
</tbody>
</table>
... Other parameters.

values An array of values; rows correspond to slider positions. Alternatively, NULL; the generated function takes a single value or array of values and applies them directly.

entries, properties, objs, prefixes Vectors describing the columns of values.

param Parameter values corresponding to each row of values.

interp Whether to interpolate values. If FALSE, the Javascript function will expect non-negative integer values. Ignored if values is NULL.

digits How many significant digits to emit in the Javascript code.

fn A function returned from \texttt{par3dinterp}.

from, to, steps Values where \texttt{fn} should be evaluated.

subscene Which subscene’s properties should be modified?

omitConstant If TRUE, do not set values that are constant across the range.

rename A named character vector of names of Javascript properties to modify.

fns A list containing functions returned from \texttt{par3dinterp}.

matrix A character string giving the Javascript property name of the matrix to modify.

prefix The prefix of the scene containing \texttt{matrix}.

vertices A vector of vertex numbers (1-based) within an object.

attributes A vector of attributes of a vertex, from c("x","y","z","r","g","b","a","nx","ny","nz","radius"

objid The object containing the vertices to be modified.

\texttt{r3d} \hspace{1cm} \textit{Generic 3D interface}

Description

Generic 3D interface for 3D rendering and computational geometry.
Details

R3d is a design for an interface for 3d rendering and computation without dependency on a specific rendering implementation. R3d includes a collection of 3D objects and geometry algorithms. All r3d interface functions are named *3d. They represent generic functions that delegate to implementation functions.

The interface can be grouped into 8 categories: Scene Management, Primitive Shapes, High-level Shapes, Geometry Objects, Visualization, Interaction, Transformation, Subdivision.

The rendering interface gives an abstraction to the underlying rendering model. It can be grouped into four categories:

**Scene Management:** A 3D scene consists of shapes, lights and background environment.

**Primitive Shapes:** Generic primitive 3D graphics shapes such as points, lines, triangles, quadrangles and texts.

**High-level Shapes:** Generic high-level 3D graphics shapes such as spheres, sprites and terrain.

**Interaction:** Generic interface to select points in 3D space using the pointer device.

In this package we include an implementation of r3d using the underlying rgl.* functions.

3D computation is supported through the use of object structures that live entirely in R.

**Geometry Objects:** Geometry and mesh objects allow to define high-level geometry for computational purpose such as triangle or quadrangle meshes (see mesh3d).

**Transformation:** Generic interface to transform 3d objects.

**Visualization:** Generic rendering of 3d objects such as dotted, wired or shaded.

**Computation:** Generic subdivision of 3d objects.

At present, the main practical differences between the r3d functions and the rgl.* functions are as follows.

The r3d functions call open3d if there is no device open, and the rgl.* functions call rgl.open. By default open3d sets the initial orientation of the coordinate system in 'world coordinates', i.e. a right-handed coordinate system in which the x-axis increases from left to right, the y-axis increases with depth into the scene, and the z-axis increases from bottom to top of the screen. rgl.* functions, on the other hand, use a right-handed coordinate system similar to that used in OpenGL. The x-axis matches that of r3d, but the y-axis increases from bottom to top, and the z-axis decreases with depth into the scene. Since the user can manipulate the scene, either system can be rotated into the other one.

The r3d functions also preserve the rgl.material setting across calls (except for texture elements, in the current implementation), whereas the rgl.* functions leave it as set by the last call.

The example code below illustrates the two coordinate systems.

Examples

```r
x <- c(0, 1, 0, 0)
y <- c(0, 0, 1, 0)
z <- c(0, 0, 0, 1)
labels <- c("Origin", "X", "Y", "Z")
i <- c(1, 2, 1, 3, 1, 4)

# rgl.* interface
rgl.open()
rgl.texts(x, y, z, labels)
rgl.texts(1, 1, 1, "rgl.* coordinates")
rgl.lines(x[i], y[i], z[i])

# *3d interface
open3d()
text3d(x, y, z, labels)
text3d(1, 1, 1, "*3d coordinates")
segments3d(x[i], y[i], z[i])
```

---

**readSTL**

*Read and write STL (stereolithography) format files*

**Description**

These functions read and write STL files. This is a simple file format that is commonly used in 3D printing. It does not represent text, only triangles. The `writeSTL` function converts some RGL object types to triangles.

**Usage**

```r
readSTL(con, ascii = FALSE, plot = TRUE, ...)
writeSTL(con, ascii = FALSE,
        pointRadius = 0.005,
        pointShape = icosahedron3d(),
        lineRadius = pointRadius,
        lineSides = 20,
        ids = tagged3d(tags),
        tags = NULL)
```

**Arguments**

- **con** A connection or filename.
- **ascii** Whether to use the ASCII format or the binary format.
- **plot** On reading, should the object be plotted?
... If plotting, other parameters to pass to `triangles3d`:

pointRadius, lineRadius

The radius of points and lines relative to the overall scale of the figure.

pointShape

A mesh shape to use for points. It is scaled by the pointRadius.

lineSides

Lines are rendered as cylinders with this many sides.

ids

The identifiers (from `ids3d`) of the objects to write. If NULL, try to write everything.

tags

Alternate way to specify ids. Ignored if ids is given.

Details

The current implementation is limited. For reading, it ignores normals and color information. For writing, it only outputs triangles, quads, planes, spheres, points, line segments, line strips and surfaces, and does not write color information. Lines and points are rendered in an isometric scale: if your data scales vary, they will look strange.

Since the STL format only allows one object per file, all RGL objects are combined into a single object when output.

The output file is readable by Blender and Meshlab; the latter can write in a number of other formats, including U3D, suitable for import into a PDF document.

Value

`readSTL` invisibly returns the object id if `plot = TRUE`, or (visibly) a matrix of vertices of the triangles if not.

`writeSTL` invisibly returns the name of the connection to which the data was written.

Author(s)

Duncan Murdoch

References

The file format was found on Wikipedia on October 25, 2012. I learned about the STL file format from David Smith’s blog reporting on Ian Walker’s `r2stl` function.

See Also

`scene3d` saves a copy of a scene to an R variable; `rglwidget, writeASY, writePLY, writeOBJ` and `writeSTL` write the scene to a file in various other formats.

Examples

```r
filename <- tempfile(fileext = "\nopen3d()
shade3d( icosahedron3d(col = "magenta") )
writeSTL(filename)
open3d()
readSTL(filename, col = "red")
```
rgl.attrib  

Get information about shapes

Description

Retrieves information about the shapes in a scene.

Usage

```r
rgl.attrib(id, attrib, first = 1,
last = rgl.attrib.count(id, attrib))
```

Arguments

- `id` A shape identifier, as returned by `ids3d`.
- `first`, `last` Specify these to retrieve only those rows of the result.

Details

If the identifier is not found or is not a shape that has the given attribute, zero will be returned by `rgl.attrib.count`, and an empty matrix will be returned by `rgl.attrib`.

The first four `attrib` names correspond to the usual OpenGL properties; "dim" is used just for surfaces, defining the rows and columns in the rectangular grid; "cex", "adj", "family", "font" and "pos" apply only to text objects.

Value

`rgl.attrib` returns the values of the attribute. Attributes are mostly real-valued, with the following sizes:

- "vertices" 3 values x, y, z
- "normals" 3 values x, y, z
- "centers" 3 values x, y, z
- "colors" 4 values r, g, b, a
- "texcoords" 2 values s, t
- "dim" 2 values r, c
- "cex" 1 value cex
- "adj" 2 values x, y
- "radii" 1 value r
- "ids" 1 value id
- "usermatrix" 4 values x, y, z, w
- "texts" 1 value text
The "texts", "types" and "family" attributes are character-valued; the "flags" attribute is logical valued, with named rows.

These are returned as matrices with the row count equal to the count for the attribute, and the columns as listed above.

Duncan Murdoch

**See Also**

ids3d, rgl.attrib.info

**Examples**

```R
p <- plot3d(rnorm(100), rnorm(100), rnorm(100), type = "s", col = "red")
grl.attrib(p["data"], "vertices", last = 10)
```

---

### rgl.attrib.info

*Get information about attributes of objects*

#### Description

These functions give information about the attributes of RGL objects. rgl.attrib.info is the more “user-friendly” function; rgl.attrib.count is a lower-level function more likely to be used in programming.

#### Usage

```R
rgl.attrib.info(id = ids3d("all", 0)$id, attrs = NULL, showAll = FALSE)
grl.attrib.count(id, attr)
```  

#### Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>One or more RGL object ids.</td>
</tr>
<tr>
<td>attrs</td>
<td>A character vector of one or more attribute names.</td>
</tr>
<tr>
<td>showAll</td>
<td>Should attributes with zero entries be shown?</td>
</tr>
<tr>
<td>attrib</td>
<td>A single attribute name.</td>
</tr>
</tbody>
</table>
rgl.bbox

Set up bounding box decoration

rgl.bbox

Set up the bounding box decoration.

Usage

rgl.bbox(
  xat = NULL, xlab = NULL, xunit = 0, xlen = 5,
  yat = NULL, ylab = NULL, yunit = 0, ylen = 5,
  zat = NULL, zlab = NULL, zunit = 0, zlen = 5,
  marklen = 15.0, marklen.rel = TRUE, expand = 1,
  draw_front = FALSE, ...)
bbox3d(xat = NULL, yat = NULL, zat = NULL,
  xunit = "pretty", yunit = "pretty", zunit = "pretty",
  expand = 1.03,
  draw_front = FALSE, ...)

Details

See the first example below to get the full list of attribute names.

Value

A dataframe containing the following columns:

id        The id of the object.
attrib    The full name of the attribute.
nrow, ncol The size of matrix that would be returned by `rgl.attrib` for this attribute.

Author(s)

Duncan Murdoch

See Also

`rgl.attrib` to obtain the attribute values.

Examples

```r
open3d()
  id <- points3d(rnorm(100), rnorm(100), rnorm(100), col = "green")
  rgl.attrib.info(id, showAll = TRUE)
  rgl.attrib.count(id, "vertices")

  merge(rgl.attrib.info(), ids3d("all"))
```
rgl.bbox

Arguments

- `xat, yat, zat` vector specifying the tickmark positions
- `xlab, ylab, zlab` character vector specifying the tickmark labeling
- `xunit, yunit, zunit` value specifying the tick mark base for uniform tick mark layout
- `xlen, ylen, zlen` value specifying the number of tickmarks
- `marklen` value specifying the length of the tickmarks
- `marklen.rel` logical, if TRUE tick mark length is calculated using 1/marklen * axis length, otherwise tick mark length is marklen in coordinate space
- `expand` value specifying how much to expand the bounding box around the data
- `draw_front` draw the front faces of the bounding box
- `...` Material properties (or other rgl.bbox parameters in the case of bbox3d). See rgl.material for details.

Details

Four different types of tick mark layouts are possible. This description applies to the X axis; other axes are similar: If `xat` is not NULL, the ticks are set up at custom positions. If `xunit` is numeric but not zero, it defines the tick mark base. If it is "pretty" (the default in bbox3d), ticks are set at pretty locations. If `xlen` is not zero, it specifies the number of ticks (a suggestion if `xunit` is "pretty").

The first color specifies the bounding box, while the second one specifies the tick mark and font color.

bbox3d defaults to pretty locations for the axis labels and a slightly larger box, whereas rgl.bbox covers the exact range.

axes3d offers more flexibility in the specification of the axes, but they are static, unlike those drawn by rgl.bbox and bbox3d.

Value

This function is called for the side effect of setting the bounding box decoration. A shape ID is returned to allow pop3d to delete it.

See Also

- rgl.material, axes3d

Examples

```r
rgl.open()
rgl.points(rnorm(100), rnorm(100), rnorm(100))
rgl.bbox(color = c("#333377", "white"), emission = "#333377",
        specular = "#3333FF", shininess = 5, alpha = 0.8 )
```
rgl.bringtotop

Assign focus to an RGL window

Description

'rgl.bringtotop' brings the current RGL window to the front of the window stack (and gives it focus).

Usage

rgl.bringtotop(stay = FALSE)

Arguments

stay

whether to make the window stay on top.

Details

If stay is TRUE, then the window will stay on top of normal windows.

Note

not completely implemented for X11 graphics (stay not implemented; window managers such as KDE may block this action (set "Focus stealing prevention level" to None in Control Center/Window Behavior/Advanced)). Not currently implemented under OS/X.

Author(s)

Ming Chen/Duncan Murdoch

Examples

rgl.open()
rgl.points(rnorm(1000), rnorm(1000), rnorm(1000), color = heat.colors(1000))
rgl.bringtotop(stay = TRUE)
rgl.init  Initializing RGL

Description

Initializing the RGL system.

Usage

rgl.init(initValue = 0, onlyNULL = FALSE,
       debug = getOption("rgl.debug", FALSE))

Arguments

initValue value for internal use only
onlyNULL only initialize the null (no display) device
debug enable some debugging messages

Details

If useNULL is TRUE, RGL will use a “null” device. This device records objects as they are plotted, but displays nothing. It is intended for use with rglwidget and similar functions.

Currently debug only controls messages printed by the OpenGL library during initialization. In future debug = TRUE may become more verbose.

For display within an OpenGL window in R, RGL requires the OpenGL system to be installed and available. If there is a problem initializing it, you may see the message ‘rgl.init’ failed, running with ‘rgl.useNULL = TRUE’. There are several causes and remedies:

- On any system, the OpenGL libraries need to be present for RGL to be able to start an OpenGL device.
  - On macOS, you need to install XQuartz. It is available from https://www.xquartz.org.
  - On Linux, you need to install Mesa 3D. One of these commands may work, depending on your system:
    - zypper source-install --build-deps-only Mesa # openSUSE/SLED/SLES
    - yum-builddep mesa # yum Fedora, OpenSuse(?)
    - dnf builddep mesa # dnf Fedora
    - apt-get build-dep mesa # Debian, Ubuntu and related

- Windows should have OpenGL installed by default.

- On Unix-alike systems (macOS and Linux, for example), RGL normally uses the GLX system for creating displays. If the graphic is created on a remote machine, it may need to use “Indirect GLX” (IGLX). Due to security concerns, this is often disabled by default. See https://www.x.org/wiki/Development/Security/Advisory-2014-12-09/ for a discussion of the security issues, and https://unix.stackexchange.com/q/317954 for ways to re-enable IGLX.
The [https://www.virtualgl.org](https://www.virtualgl.org) project is intended to be a way to avoid IGLX, by rendering remotely and sending bitmaps to the local machine. It’s not a simple install...

- If you don’t need to see RGL displays on screen, you can use the “NULL device”. See `rgl.useNULL`.

- If you can’t build the `rgl` package with OpenGL support, you can disable it and use the NULL device. (This may happen automatically during configuration, but you’ll get a tested result if you specify it explicitly.) See the instructions in the ‘README’ file in the source tarball.

**Value**

Normally the user doesn’t call `rgl.init` at all: it is called when the package is loaded. It returns no useful value.

```r
rgl.material

Description

Set material properties for geometry appearance.

Usage

```r
rgl.material(
  color = "white",
  alpha = 1.0,
  lit = TRUE,
  ambient = "black",
  specular = "white",
  emission = "black",
  shininess = 50.0,
  smooth = TRUE,
  texture = NULL,
  textype = "rgb",
  texmipmap = FALSE,
  texminfilter = "linear",
  texmagfilter = "linear",
  texenvmap = FALSE,
  front = "fill",
  back = "fill",
  size = 3.0,
  lwd = 1.0,
  fog = TRUE,
  point_antialias = FALSE,
  line_antialias = FALSE,
  depth_mask = TRUE,
  depth_test = "less",
```
rgl.material

polygon_offset = c(0.0, 0.0),
margin   = "",
floating = FALSE,
tag      = "",
...
)
material3d(...)
"lines"  wireframed polygon
"points"  point polygon
"culled"  culled (hidden) polygon

size  numeric, specifying the size of points in pixels
lwd  numeric, specifying the line width in pixels
fog  logical, specifying if fog effect should be applied on the corresponding shape. Fog type is set in bg3d.

point_antialias, line_antialias
  logical, specifying if points should be round and lines should be antialiased, but see Note below.

depth_mask  logical, specifying whether the object's depth should be stored.
depth_test  Determines which depth test is used to see if this object is visible, depending on its apparent depth in the scene compared to the stored depth. Possible values are "never", "less" (the default), "equal", "lequal" (less than or equal), "greater", "notequal", "gequal" (greater than or equal), "always".

polygon_offset  If non-zero, offsets are added to the recorded depth of filled polygons. See Details below.

margin, floating
  Used mainly for text to draw annotations in the margins, but supported by most kinds of objects: see mtext3d.

tag  A length 1 string value. These may be used to identify objects, or encode other meta data about the object.

...  Any of the arguments above can be passed to material3d; see Details below. rgl.material will ignore others.

Details

Values can be queried by specifying their names in a character vector, e.g. material3d("color"). There is one read-only property that can be queried but not set:

isTransparent  Is the current color transparent?

Only one side at a time can be culled.

Object display colors are determined as follows:

- If lit = FALSE, an element of the color vector property is displayed without modification. See documentation for individual objects for information on which element is chosen.
- If lit = TRUE, the color is determined as follows.
  1. The color is set to the emission property of the object.
  2. For each defined light, the following are added:
     - the product of the ambient color of the light and the ambient color of the object is added.
     - the color of the object is multiplied by the diffuse color of the light and by a constant depending on the angle between the surface and the direction to the light, and added.
the specular color of the object is multiplied by the specular color of the light
and a constant depending on the shininess of the object and the direction to the
light, and added. The shininess property mainly determines the size of the shiny
highlight; adjust one or both of the specular colors to change its brightness.

The polygon_offset property is a two element vector giving the ‘factor’ and ‘units’ values
to use in a glPolygonOffset() call in OpenGL. If only one value is given, it is used for both
elements. The ‘units’ value is added to the depth of all pixels in a filled polygon, and the ‘factor’
value is multiplied by an estimate of the slope of the polygon and then added to the depth. Positive
values “push” polygons back slightly for the purpose of depth testing, to allow points, lines or other
polygons to be drawn on the surface without being obscured due to rounding error. Negative values
pull the object forward. A typical value to use is 1 (which is automatically expanded to c(1,1)). If
values are too large, objects which should be behind the polygon will show through, and if values
are too small, the objects on the surface will be partially obscured. Experimentation may be needed
to get it right. The first example in ?persp3d uses this property to add grid lines to a surface.

material3d is an alternate interface to the material properties, modelled after par3d: rather than
setting defaults for parameters that are not specified, they will be left unchanged. material3d may
also be used to query the material properties; see the examples below.

The current implementation does not return parameters for textures.

The material member of the r3dDefaults list may be used to set default values for material
properties.

The ... parameter to rgl.material is ignored.

Value

rgl.material() is called for the side effect of setting the material properties. It returns a value
invisibly which is not intended for use by the user.

Users should use material3d() to query material properties. It returns values similarly to par3d
as follows: When setting properties, it returns the previous values in a named list. A named list is
also returned when more than one value is queried. When a single value is queried it is returned
directly.

Note

If point_antialias is TRUE, points will be drawn as circles in WebGL; otherwise, they will be
drawn as squares. Within R, the behaviour depends on your graphics hardware: for example, I see
circles for both settings on my laptop.

Within R, lines tend to appear heavier with line_antialias == TRUE. There’s no difference at all
in WebGL.

Examples

save <- material3d("color")
material3d(color = "red")
material3d("color")
material3d(color = save)

# this illustrates the effect of depth_test
x <- c(1:3); xmid <- mean(x)
y <- c(2, 1, 3); ymid <- mean(y)
z <- 1
open3d()
tests <- c("never", "less", "equal", "lequal", "greater",
            "notequal", "gequal", "always")
for (i in 1:8) {
  triangles3d(x, y, z + i, col = heat.colors(8)[i])
  texts3d(xmid, ymid, z + i, paste(i, tests[i], sep = "."), depth_test = tests[i])
}
highlevel()  # To trigger display

---

rgl.open  

Low level window interface

Description

3D real-time rendering system.

Usage

rgl.open(useNULL = rgl.useNULL())  # open new device
rgl.close()  # close current device
rgl.cur()  # returns active device ID
rgl.dev.list()  # returns all device IDs
rgl.set(which, silent = FALSE)  # set device as active
rgl.quit()  # shutdown RGL device system

Arguments

useNULL  whether to open the “null” device
which  device ID
silent  whether to suppress update of window titles

Details

The RGL device design is oriented towards the R device metaphor. If you send scene management instructions, and there’s no device open, it will be opened automatically. Opened devices automatically get the current device focus. The focus may be changed by using rgl.set(). rgl.quit() shuts down the RGL subsystem and all open devices, detaches the package including the shared library and additional system libraries.

The rgl.open() function attempts to open a new RGL window. If the "rgl.antialias" option is set, it will be used to select the requested antialiasing. (See open3d for more description of antialiasing and an alternative way to set the value.)
If `useNULL` is `TRUE`, RGL will use a “null” device. This device records objects as they are plotted, but displays nothing. It is intended for use with `rglwidget` and similar functions.

If `rgl.open()` fails (e.g. because X windows is not running, or its `DISPLAY` variable is not set properly), then you can retry the initialization by calling `rgl.init()`. Do not do this when windows have already been successfully opened: they will be orphaned, with no way to remove them other than closing R. In fact, it’s probably a good idea not to do this at all: quitting R and restarting it is a better solution.

This package also includes a higher level interface which is described in the `r3d` help topic. That interface is designed to act more like classic 2D R graphics. We recommend that you avoid mixing `rgl.*` and `*3d` calls.

**Value**

`rgl.open`, `rgl.close` and `rgl.set` are called for their side effects and return no useful value. Similarly `rgl.quit` is not designed to return useful values; in fact, users shouldn’t call it at all!

`rgl.cur` returns the currently active devices, or 0 if none is active; `rgl.dev.list` returns a vector of all open devices. Both functions name the items according to the type of device: `null` for a hidden null device, `wgl` for a Windows device, and `glX` for an X windows device.

**See Also**

---

**rgl.pixels**

*Extract pixel information from window*

**Description**

This function extracts single components of the pixel information from the topmost window.

**Usage**

```r
rgl.pixels(component = c("red", "green", "blue"),
           viewport = par3d("viewport"), top = TRUE)
```

**Arguments**

- `component` Which component(s)?
- `viewport` Lower left corner and size of desired region.
- `top` Whether to bring window to top before reading.
Details

The possible components are "red", "green", "blue", "alpha", "depth", and "luminance" (the sum of the three colors). All are scaled from 0 to 1.

Note that the luminance is kept below 1 by truncating the sum; this is the definition used for the GL_LUMINANCE component in OpenGL.

Value

A vector, matrix or array containing the desired components. If one component is requested, a vector or matrix will be returned depending on the size of block requested (length 1 dimensions are dropped); if more, an array, whose last dimension is the list of components.

rgl.snapshot to write a copy to a file, demo("stereo") for functions that make use of this to draw a random dot stereogram and an anaglyph.

Examples

e.example(surface3d)
depth <- rgl.pixels(component = "depth")
if (length(depth) && is.matrix(depth)) # Protect against empty or single pixel windows
  contour(depth)

rgl.postscript

Export vector graphics

Description

Saves the screenshot to a file in PostScript or other vector graphics format.

Usage

rgl.postscript( filename, fmt = "eps", drawText = TRUE )

Arguments

filename full path to filename.
fmt export format, currently supported: ps, eps, tex, pdf, svg, pgf
drawText logical, whether to draw text
Details

Animations can be created in a loop modifying the scene and saving a screenshot to a file. (See example below)

This function is a wrapper for the GL2PS library by Christophe Geuzaine, and has the same limitations as that library: not all OpenGL features are supported, and some are only supported in some formats. See the reference for full details.

### rgl.select

*Switch to select mode, and return the mouse position selected*

**Description**

Mostly for internal use, this function temporarily installs a handler on a button of the mouse that will return the mouse coordinates of one click and drag rectangle.

**Usage**

```r
rgl.select(button = c("left", "middle", "right"),
            dev = cur3d(), subscene = currentSubscene3d(dev))
```

**Arguments**

- **button**
  - Which button to use?

- **dev, subscene**
  - The RGL device and subscene to work with

**Value**

A vector of four coordinates: the X and Y coordinates of the start and end of the dragged rectangle.

**Author(s)**

Duncan Murdoch

**See Also**

- `rgl.select3d`, a version that allows the selection region to be used to select points in the scene.
rgl.setAxisCallback  

**User-defined axis labelling callbacks.**

### Description

These are low level functions to set or get user-defined axis labelling callbacks in R.

### Usage

```r
rgl.setAxisCallback(axis, draw = NULL,
                     dev = cur3d(), subscene = currentSubscene3d(dev))
```

```r
rgl.getAxisCallback(axis, dev = cur3d(), subscene = currentSubscene3d(dev))
```

### Arguments

- **axis**
  Which axis? Can be value from 1:3.

- **draw**
  The function to draw the axis. See Details below.

- **dev, subscene**
  The RGL device and subscene to work with.

### Details

This function only works if a bounding box decoration (set by `bbox3d`, for example) exists. When it tries to label the axis specified in `rgl.setAxisCallback`, it will call `draw`, which is assumed to be a function with header `function(margin)`.

The `margin` argument will be a single string like "x++", indicating that RGL is drawing the x axis, and suggests putting it on the edge represented by the high values of the other two axes. The function may use `par3d("bbox")` to determine the current size of the bounding box and should draw an appropriate axis. See `mtext3d` for a discussion of drawing in the margins.

The box outlining the plot region will always be drawn, but can be made invisible by setting `front = "cull", back = "cull"` in the call to `bbox3d`.

### Value

Called for the side effect of setting the callback. The set function returns NULL invisibly.

### Author(s)

Duncan Murdoch

### See Also

- `setAxisCallbacks` to work with `rglwidget`. 
Examples

datelabels <- local({
    id <- 0
    bbox <- NULL

    function(margin) {
        # Only need to redraw when the bbox changes
        if (!identical(bbox, par3d("bbox"))) {
            if (id > 0)
                pop3d(id = id)
            axis <- match(substr(margin, 1, 1), c("x", "y", "z"))
            range <- as.Date(par3d("bbox"))[2*axis + (-1):0],
                    origin = "1970-01-01")
            where <- pretty(range)
            where <- where[range[1] <= where & where <= range[2]]
            id <<- mtext3d(format(where, format="%b %d"), margin, at = where, line = 1)
            bbox <<- par3d("bbox")
        }
    }
})

# This doesn't work in WebGL displays

if (!in_pkgdown_example()) {

    # The default plots dates numerically:
    plot3d(xyz, xlab = "Date", ylab = "y", zlab = "z")
    rgl.setAxisCallback(1, datelabels)
    # Repeat the data 5 days later
    points3d(xyz + rep(c(5, 0, 0), each = 10))
    # Make the plot square again
    aspect3d(1,1,1)
}

rgl.setMouseCallbacks  User callbacks on mouse events

Description

Set and get user callbacks on mouse events.

Usage

  rgl.setMouseCallbacks(button, begin = NULL, update = NULL, end = NULL,
                        dev = cur3d(), subscene = currentSubscene3d(dev))
rgl.setMouseCallbacks

rgl.getMouseCallbacks(button,
    dev = cur3d(), subscene = currentSubscene3d(dev))

rgl.setWheelCallback(rotate,
    dev = cur3d(), subscene = currentSubscene3d(dev))

rgl.getWheelCallback(dev = cur3d(), subscene = currentSubscene3d(dev))

Arguments

button Which button? Use 1 for left, 2 for right, 3 for middle, 4 for wheel. Use 0 to set an action when no button is pressed.
begin Called when mouse down event occurs
update Called when mouse moves
end Called when mouse is released
rotate Called when mouse wheel is rotated
dev, subscene The RGL device and subscene to work with

Details

The set functions set event handlers on mouse events that occur within the current RGL window. The begin and update events should be functions taking two arguments; these will be the mouse coordinates when the event occurs. The end event handler takes no arguments. The rotate event takes a single argument, which will be equal to 1 if the user pushes the wheel away by one click, and 2 if the user pulls the wheel by one click.

Alternatively, the handlers may be set to NULL, the default value, in which case no action will occur.

If a subscene has multiple listeners, the user action will still only be called for the subscene that received the mouse event. It should consult par3d("listeners") if it makes sense to take action on the whole group of subscenes.

The get function retrieves the callbacks that are currently set.

The “no button” mouse handler may be set by specifying button = 0. The begin function will be called the first time the mouse moves within the subscene, and the update function will be called repeatedly as it moves. The end function will never be called.

Value

The set functions are called for the side effect of setting the mouse event handlers.

The rgl.getMouseCallbacks function returns a list containing the callback functions or NULL if no user callback is set. The rgl.getWheelCallback returns the callback function or NULL.

par3d to set built-in handlers, setUserCallbacks to work with rglwidget.

Examples

```r
pan3d <- function(button, dev = cur3d(), subscene = currentSubscene3d(dev)) {
  start <- list()

  begin <- function(x, y) {
    activeSubscene <- par3d("activeSubscene", dev = dev)
    start$listeners <<- par3d("listeners", dev = dev, subscene = activeSubscene)
    for (sub in start$listeners) {
      init <- par3d(c("userProjection","viewport"), dev = dev, subscene = sub)
      init$pos <- c(x/init$viewport[3], 1 - y/init$viewport[4], 0.5)
      start[[as.character(sub)]] <<- init
    }
  }

  update <- function(x, y) {
    for (sub in start$listeners) {
      init <- start[[as.character(sub)]]
      xlat <- 2*(c(x/init$viewport[3], 1 - y/init$viewport[4], 0.5) - init$pos)
      mouseMatrix <- translationMatrix(xlat[1], xlat[2], xlat[3])
      par3d(userProjection = mouseMatrix %*% init$userProjection, dev = dev, subscene = sub)
    }
  }

  rgl.setMouseCallbacks(button, begin, update, dev = dev, subscene = subscene)
  cat("Callbacks set on button", button, "of RGL device", dev, "in subscene", subscene, "\n")
}

open3d()
shade3d(icosahedron3d(), col = "yellow")
# This only works in the internal display...
pan3d(1)
```

rgl.surface

Add surface (obsolete)

Description

Adds a surface to the current scene. The surface is defined by a matrix defining the height of each grid point and two vectors defining the grid.

Usage

```r
rgl.surface(x, z, y, coords = 1:3, ...,
  normal_x = NULL, normal_y = NULL, normal_z = NULL,
  texture_s = NULL, texture_t = NULL)
```
rgl.surface

Arguments

- **x**
  values corresponding to rows of \( y \), or matrix of \( x \) coordinates

- **y**
  matrix of height values

- **z**
  values corresponding to columns of \( y \), or matrix of \( z \) coordinates

- **coords**
  See details

- ... Material and texture properties. See rgl.material for details.

- **normal_x, normal_y, normal_z**
  matrices of the same dimension as \( y \) giving the coordinates of normals at each grid point

- **texture_s, texture_t**
  matrices of the same dimension as \( z \) giving the coordinates within the current texture of each grid point

Details

Adds a surface mesh to the current scene. The surface is defined by the matrix of height values in \( y \), with rows corresponding to the values in \( x \) and columns corresponding to the values in \( z \).

The `coords` parameter can be used to change the geometric interpretation of \( x \), \( y \), and \( z \). The first entry of `coords` indicates which coordinate (1 = \( X \), 2 = \( Y \), 3 = \( Z \)) corresponds to the \( x \) parameter. Similarly the second entry corresponds to the \( y \) parameter, and the third entry to the \( z \) parameter. In this way surfaces may be defined over any coordinate plane.

If the normals are not supplied, they will be calculated automatically based on neighbouring points. Texture coordinates run from 0 to 1 over each dimension of the texture bitmap. If texture coordinates are not supplied, they will be calculated to render the texture exactly once over the grid. Values greater than 1 can be used to repeat the texture over the surface.

`rgl.surface` always draws the surface with the ‘front’ upwards (i.e. towards higher \( y \) values). This can be used to render the top and bottom differently; see `rgl.material` and the example below.

If the \( x \) or \( z \) argument is a matrix, then it must be of the same dimension as \( y \), and the values in the matrix will be used for the corresponding coordinates. This is used to plot shapes such as cylinders where \( y \) is not a function of \( x \) and \( z \).

NA values in the height matrix are not drawn.

Value

The object ID of the displayed surface is returned invisibly.

Note

It is recommended to use `surface3d` instead of `rgl.surface`; use of the `rgl.*` functions is discouraged due to their side effects.

See Also

`rgl.material, surface3d, terrain3d`. See `persp3d` for a higher level interface.
Examples

# volcano example taken from "persp"
#
data(volcano)

y <- 2 * volcano  # Exaggerate the relief

x <- 10 * (1:nrow(y))  # 10 meter spacing (S to N)
z <- 10 * (1:ncol(y))  # 10 meter spacing (E to W)

ylim <- range(y)

colorlut <- terrain.colors(ylen)  # height color lookup table

col <- colorlut[ y - ylim[1] + 1 ]  # assign colors to heights for each point

rgl.open()
rgl.surface(x, z, y, color = col, back = "lines")

descript
When the RGL device is closed at the end of the code chunk, `rgl.Sweave.off()` will be called automatically. It will save a snapshot of the last image (by default in `.png` format) for inclusion in the Sweave document and (by default) close the device. Alternatively, the `Sweave.snapshot()` function can be called to save the image before the end of the chunk. Only one snapshot will be taken per chunk.

Several chunk options are used by the `rgl.Sweave` device:

- **stayopen** (default `FALSE`). If `TRUE` then the RGL device will *not* be closed at the end of the chunk, instead a call to `Sweave.snapshot()` will be used if it has not been called explicitly. Subsequent chunks can add to the scene.

- **outputtype** (default `png`). The output may be specified as `outputtype = pdf` or `outputtype = eps` instead, in which case the `rgl.postscript()` function will be used to write output in the specified format. Note that `rgl.postscript()` has limitations and does not always render scenes correctly.

- **delay** (default `0.1`). After creating the display window, `Sys.sleep()` will be called to delay this many seconds, to allow the display system to initialize. This is needed in X11 systems which open the display asynchronously. If the default time is too short, `rgl.Sweave` may falsely report that the window is too large to open.

**Value**

These functions are called for their side effects.

**Note**

We recommend turning off all other graphics drivers in a chunk that uses `grdevice = rgl.Sweave`. The RGL functions do not write to a standard graphics device.

**Note**

The `rgl` package relies on your graphics hardware to render OpenGL scenes, and the default `.png` output copies a bitmap from the hardware device. All such devices have limitations on the size of the bitmap, but they do not always signal these limitations in a way that RGL will detect. If you find that images are not being produced properly, try reducing the size using the `resolution`, `width` or `height` chunk options.

**Author(s)**

Duncan Murdoch

**See Also**

`RweaveLatex` for a description of alternate graphics drivers in Sweave, and standard options that can be used in code chunks.

`hook_rgl` and `hook_webgl` allow fixed or interactive RGL scenes to be embedded in `knitr` documents.
rgl.texts  

Low-level functions for plotting text

Description

This is a low-level function for plotting text. Users should normally use the high-level function text3d instead.

Usage

rgl.texts(x, y = NULL, z = NULL, text, 
adj = 0.5, pos = NULL, offset = 0.5, 
family = par3d("family"), font = par3d("font"), 
cex = par3d("cex"), useFreeType = par3d("useFreeType"), ...) 
rglFonts(...)

Arguments

x, y, z  
point coordinates. Any reasonable way of defining the coordinates is acceptable. See the function xyz.coords for details.

text  
text character vector to draw

adj  
one value specifying the horizontal adjustment, or two, specifying horizontal and vertical adjustment respectively, or three, specifying adjustment in all three directions.

pos  
a position specifier for the text. If specified, this overrides any adj value given. Values of 0, 1, 2, 3, 4, 5 and 6 respectively indicate positions on, below, to the left of, above, to the right of, in front of and behind the specified coordinates.

offset  
when pos is specified, this value gives the offset of the label from the specified coordinate in fractions of a character width.

family  
A device-independent font family name, or ""

font  
A numeric font number from 1 to 4

cex  
A numeric character expansion value

useFreeType  
logical. Should FreeType be used to draw text? (See details below.)

...  
In rgl.texts, material properties; see rgl.material for details. In rglFonts, device dependent font definitions for use with FreeType.

Details

The adj parameter determines the position of the text relative to the specified coordinate. Use adj = c(0, 0) to place the left bottom corner at (x, y, z), adj = c(0.5, 0.5) to center the text there, and adj = c(1, 1) to put the right top corner there. All coordinates default to 0.5. Placement is done using the "advance" of the string and the "ascent" of the font relative to the baseline, when these metrics are known.
**Value**

`rgl.texts` returns the object ID of the text object (or sprites, in case of `usePlotmath = TRUE`) invisibly.

`rglFonts` returns the current set of font definitions.

**Fonts**

Fonts are specified using the `family`, `font`, `cex`, and `useFreeType` arguments. Defaults for the currently active device may be set using `par3d`, or for future devices using `r3dDefaults`.

The `family` specification is the same as for standard graphics, i.e. families `c("serif","sans","mono","symbol")` are normally available, but users may add additional families. `font` numbers are restricted to the range 1 to 4 for standard, bold, italic and bold italic respectively. Font 5 is recoded as family "symbol" font 1, but that is not supported unless specifically installed, so should be avoided.

Using an unrecognized value for "family" will result in the system standard font as used in RGL up to version 0.76. That font is not resizable and font values are ignored.

If `useFreeType` is `TRUE`, then RGL will use the FreeType anti-aliased fonts for drawing. This is generally desirable, and it is the default on non-Windows systems if RGL was built to support FreeType.

FreeType fonts are specified using the `rglFonts` function. This function takes a vector of four filenames of TrueType font files which will be used for the four styles regular, bold, italic and bold italic. The vector is passed with a name to be used as the family name, e.g. `rglFonts(sans = c("/path/to/FreeSans.ttf",...))`. In order to limit the file size, the `rgl` package ships with just 3 font files, for regular versions of the serif, sans and mono families. Additional free font files were available in the past from the Amaya project, though currently the `rglExtrafonts` function provides an easier way to register new fonts.

On Windows the system fonts are acceptable and are used when `useFreeType = FALSE` (the current default in `r3dDefaults`). Mappings to family names are controlled by the `grDevices::windowsFonts()` function.

Full pathnames should normally be used to specify font files. If relative paths are used, they are interpreted differently by platform. Currently Windows fonts are looked for in the Windows fonts folder, while other platforms use the current working directory.

If FreeType fonts are not used, then bitmapped fonts will be used instead. On Windows these will be based on the fonts specified using the `windowsFonts` function, and are resizable. Other platforms will use the default bitmapped font which is not resizable.

Bitmapped fonts have a limited number of characters supported; if any unsupported characters are used, an error will be thrown.

**Examples**

```## Not run:
# These FreeType fonts are available from the Amaya project, and are not shipped
# with rgl. You would normally install them to the rgl/fonts directory
# and use fully qualified pathnames, e.g.
# system.file("fonts/FreeSerif.ttf", package = "rgl")```
rglFonts(serif = c("FreeSerif.ttf", "FreeSerifBold.ttf", "FreeSerifItalic.ttf", "FreeSerifBoldItalic.ttf"),
mono = c("FreeMono.ttf", "FreeMonoBold.ttf", "FreeMonoOblique.ttf", "FreeMonoBoldOblique.ttf"),
symbol= c("ESSTIX10.TTF", "ESSTIX12.TTF", "ESSTIX9..TTF", "ESSTIX11.TTF"))

## End(Not run)

---

### rgl.useNULL

**Report default use of null device**

**Description**

This function checks the "rgl.useNULL" option if present, or the RGL_USE_NULL environment variable if it is not. If the value is TRUE or a string which matches "yes" or "true" in a case-insensitive test, TRUE is returned.

**Usage**

```r
rgl.useNULL()
```

**Value**

A logical value indicating the current default for use of the null device.

**Note**

This function is checked by the initialization code when the `rgl` package is loaded. Thus if you want to run RGL on a system where there is no graphics support, you should run `options(rgl.useNULL = TRUE)` or set the environment variable RGL_USE_NULL=TRUE *before* calling `library(rgl)` (or other code that loads `rgl`), and it will not fail in its attempt at initialization.

**Author(s)**

Duncan Murdoch

**See Also**

`open3d` and `rgl.open`.

**Examples**

```r
rgl.useNULL()
```
rgl.user2window  

Convert between RGL user and window coordinates

Description
This function converts from 3-dimensional user coordinates to 3-dimensional window coordinates.

Usage

```r
glm.user2window(x, y = NULL, z = NULL, projection = rgl.projection())
glm.window2user(x, y = NULL, z = 0, projection = rgl.projection())
```

details

Arguments

- `x, y, z` 
  Input coordinates. Any reasonable way of defining the coordinates is acceptable. See the function `xyz.coords` for details.

- `projection` 
  The RGL projection to use

- `dev, subscene` 
  The RGL device and subscene to work with

Details

These functions convert between user coordinates and window coordinates.

Window coordinates run from 0 to 1 in X, Y, and Z. X runs from 0 on the left to 1 on the right; Y runs from 0 at the bottom to 1 at the top; Z runs from 0 foremost to 1 in the background. RGL does not currently display vertices plotted outside of this range, but in normal circumstances will automatically resize the display to show them. In the example below this has been suppressed.

Value

The coordinate conversion functions produce a matrix with columns corresponding to the X, Y, and Z coordinates.

`rgl.projection()` returns a list containing the following components:

- `model` 
  the modelview matrix

- `projection` 
  the projection matrix

- `viewport` 
  the viewport vector

See `par3d` for more details.

`select3d`
Examples

```r
call3d()
points3d(rnorm(100), rnorm(100), rnorm(100))
if (interactive() || !.Platform$OS == "unix") {
  # Calculate a square in the middle of the display and plot it
  square <- rgl.window2user(c(0.25, 0.25, 0.75, 0.75, 0.25),
                           c(0.25, 0.75, 0.75, 0.25, 0.25), 0.5)
  par3d(ignoreExtent = TRUE)
  lines3d(square)
  par3d(ignoreExtent = FALSE)
}
```

rglExtrafonts  

Register extra fonts

Description

This function uses the `extrafont` package to help register system fonts for use with FreeType in `rgl`.

Usage

```r
rglExtrafonts(..., quiet = TRUE)
```

Arguments

- `...`  
  - Vectors of fonts to try. See the Details.
- `quiet`  
  - Whether to print information on progress.

Details

The `extrafont` package collects information on installed fonts from the system. When you first install `extrafont`, or after new fonts have been installed on your system, run `extrafont::font_import()` to build its database of system fonts.

Fonts can be installed in `rgl` using `rglExtrafonts(rglname = famillyname)` or `rglExtrafonts(familyname)`. In this call `familyname` is a vector of family names to look for in the `extrafont` database using `extrafont::choose_font(familyname)`; the first one found will be registered with `rgl`. The optional name `rglname` will also be usable to refer to the font family.

If none of the given family names is found, no change will be made to the registered fonts in `rgl`.

During startup, `rgl` detects whether `extrafont` is installed, and if so runs `rglExtrafonts(sans = c("Helvetica", "Arial"), serif = c("Times", "Times New Roman"), mono = c("Courier", "Courier New"))` to attempt to set up the default fonts.

Fonts found by `extrafont` can also be used in some other graphics devices besides `rgl`; see the `extrafont` documentation for details.
Value

Invisibly returns a vector giving the \texttt{rgl} name and the family name for the newly installed font.

Note

Each font in a display needs a unique \texttt{rgl} name; if the associated font for a given name is changed, all previously plotted text will also change.

Currently \texttt{rglwidget} displays will not respect the new definitions.

Author(s)

Duncan Murdoch

See Also

text3d, rglFonts

Examples

if (requireNamespace("extrafont") && !in_pkgdown_example()) {
  open3d()
  text3d(1,1,1, "Default", family = "sans", cex = 2)

  # Attempt to register new sans-serif font:
  newfamily <- rglExtrafonts(newsans = c("Comic Sans MS", "Impact",
                                      "Verdana", "Tahoma"))

  text3d(2,2,2, newfamily, family = "newsans", cex = 2)
}

\begin{itemize}
\item \textbf{rglIds} \hspace{2cm} \textit{RGL id values}
\end{itemize}

Description

All objects in an RGL scene have a numerical id. These ids are normally stored in vectors of class \texttt{c("rglIds","numeric")}, which will also have class \texttt{"rglHighlevel"} or \texttt{"rglLowlevel"} depending on whether a high level function like \texttt{plot3d} or \texttt{persp3d}, or a low level function created the objects.
rglIds

Usage

rglId(ids = integer())
lowlevel(ids = integer())
highlevel(ids = integer())
# S3 method for class 'rglId'
print(x,
   rglwidget = getOption("rgl.printRglwidget", FALSE),
   ...)

Arguments

ids     A vector of object ids.
x       An "rglId" object to print.
rglwidget  Whether to create and print an RGL widget. If false, nothing is printed.
...     Other arguments which will be passed to rglwidget if it is used.

Details

These functions and classes are intended to allow RGL scenes to be automatically displayed in R Markdown documents. See setupKnitr for details on enabling auto-printing.

Note that all objects in the current scene will be printed by default, not just the ids in x. (One reason for this is that lights are also objects; printing objects without lights would rarely make sense.)

Value

Objects of class "rglId", c("rglHighlevel","rglId","numeric") or c("rglLowlevel","rglId","numeric") for rglId, lowlevel or highlevel respectively.

Author(s)

Duncan Murdoch

Examples

x <- matrix(rnorm(30), ncol = 3, dimnames = list(NULL, c("x", "y", "z")))
p <- plot3d(x, type = "s")
str(p)
if (interactive() || in_pkdwn_example())
   print(p, rglwidget = TRUE)
rglMouse

Generate HTML code to select mouse mode

Description

This generates an HTML select element to choose among the mouse modes supported by rglwidget.

Usage

```r
glmouse(sceneId, 
  choices = c("trackball", "selecting", 
    "xAxis", "yAxis", "zAxis", 
    "polar", "zoom", "fov", 
    "none"), 
  labels = choices, 
  button = 1, 
  dev = cur3d(), 
  subscene = currentSubscene3d(dev), 
  default = par3d("mouseMode", dev = dev, subscene = subscene)[button], 
  stayActive = FALSE, 
  height = 40, 
  ...
)
```

Arguments

- **sceneId**: Either an rglwidget or the elementId from one of them.
- **choices**: Which mouse modes to support?
- **labels**: How to label each mouse mode.
- **button**: Which mouse button is being controlled.
- **dev**: The RGL device used for defaults.
- **subscene**: Which subscene is being modified.
- **default**: What is the default entry to show in the control.
- **stayActive**: Whether a selection brush should stay active if the mouse mode is changed.
- **height**: The (relative) height of the item in the output display.
- **...**: Additional arguments to pass to htmltools::tags$select(), e.g. id or class.

Details

A result of an rglwidget call can be passed as the sceneId argument. This allows the widget to be "piped" into the rglMouse call. The widget will appear first, the selector next in a tagList.

If the sceneId is a character string, it should be the elementId of a separately constructed rglwidget result.
Finally, the sceneId can be omitted. In this case the rglMouse result needs to be passed into an rglWidget call as part of the controllers argument. This will place the selector before the widget on the resulting display.

If the mouse mode is changed while brushing the scene, by default the brush will be removed (and so the selection will be cleared too). If this is not desired, set stayActive = TRUE.

Value

A browsable value to put in a web page.

Author(s)

Duncan Murdoch

Examples

```r
if (interactive() || in_pkgdown_example()) {
  open3d()
  xyz <- matrix(rnorm(300), ncol = 3)
  id <- plot3d(xyz, col = "red", type = "s")["data"]
  par3d(mouseMode = "selecting")
  share <- rglShared(id)

  # This puts the selector below the widget.
  rglWidget(shared = share, width = 300, height = 300) %>% rglMouse()

  # This puts the selector above the widget.
  rglMouse() %>% rglWidget(shared = share, width = 300, height = 300, controllers = .)
}
```

rglShared

Create shared data from an RGL object

Description

The crosstalk package provides a way for different parts of an interactive display to communicate about datasets, using “shared data” objects. When selection or filtering is performed in one view, the result is mirrored in all other views.

This function allows vertices of RGL objects to be treated as shared data.

Usage

```r
rglShared(id, key = NULL, group = NULL,
  deselectedFade = 0.1,
  deselectedColor = NULL,
  selectedColor = NULL,
  selectedIgnoreNone = TRUE,
  filteredFade = 0,
  filteredColor = NULL)
```
Arguments

- **id**: An existing RGL id.
- **key**: Optional unique labels to apply to each vertex. If missing, numerical keys will be used.
- **group**: Optional name of the shared group to which this data belongs. If missing, a random name will be generated.
- **deselectedFade, deselectedColor**: Appearance of points that are not selected. See Details.
- **selectedColor**: Appearance of points that are selected.
- **selectedIgnoreNone**: If no points are selected, should the points be shown in their original colors (TRUE), or in the deselected colors (FALSE)?
- **filteredFade, filteredColor**: Appearance of points that have been filtered out.

Details

Some functions which normally work on dataframe-like datasets will accept shared data objects in their place.

If a selection is in progress, the alpha value for unselected points is multiplied by `deselectedFade`. If `deselectedColor` is NULL, the color is left as originally specified; if not, the point is changed to the color given by `deselectedColor`.

If no points have been selected, then by default points are shown in their original colors. However, if `selectedIgnoreNone = FALSE`, all points are displayed as if unselected.

The `selectedColor` argument is similarly used to change the color (or not) of selected points, and `filteredFade` and `filteredColor` are used for points that have been filtered out of the display.

Value

An object of class "SharedData" (from the optional `crosstalk` package) which contains the x, y and z coordinates of the RGL object with the given id.

Author(s)

Duncan Murdoch

rlToLattice

Convert RGL userMatrix to lattice or base angles

Description

These functions take a user orientation matrix from an RGL scene and approximate the parameters to either lattice or base graphics functions.

Usage

rglToLattice(rotm = par3d("userMatrix"))
rglToBase(rotm = par3d("userMatrix"))

Arguments

rotm A matrix in homogeneous coordinates to convert.

Details

The lattice package can use Euler angles in the ZYX scheme to describe the rotation of a scene in its wireframe or cloud functions. The rglToLattice function computes these angles based on rotm, which defaults to the current user matrix. This allows RGL to be used to interactively find a decent viewpoint and then reproduce it in lattice.

The base graphics persp function does not use full Euler angles; it uses a viewpoint angle, and assume the z axis remains vertical. The rglToBase function computes the viewpoint angle accurately if the RGL scene is displayed with a vertical z axis, and does an approximation otherwise.
rglToLattice returns a list suitable to be used as the screen argument to wireframe.

rglToBase returns a list containing theta and phi components which can be used as corresponding arguments in persp.

Author(s)

Duncan Murdoch

Examples

```r
persp3d(volcano, col = "green")
if ((hasorientlib <- requireNamespace("orientlib", quietly = TRUE)) && requireNamespace("lattice", quietly = TRUE))
  lattice::wireframe(volcano, screen = rglToLattice())
if (hasorientlib) {
  angles <- rglToBase()
  persp(volcano, col = "green", border = NA, shade = 0.5,
    theta = angles$theta, phi = angles$phi)
}
```

rglwidget  An htmlwidget to hold an RGL scene

Description

The htmlwidgets package provides a framework for embedding graphical displays in HTML documents of various types. This function provides the necessities to embed an RGL scene in one.

Usage

```r
rglwidget(x = scene3d(minimal), width = figWidth(), height = figHeight(),
  controllers = NULL,
  elementId = NULL,
  reuse = FALSE,
  webGLOptions = list(preserveDrawingBuffer = TRUE),
  shared = NULL, minimal = TRUE,
  webgl, snapshot,
  shinyBrush = NULL,
  ...
  oldConvertBBox = FALSE)
```

Arguments

- `x` An RGL scene produced by the scene3d function.
- `width, height` The width and height of the display in pixels.
controllers Names of playwidget objects associated with this scene, or objects (typically piped in). See Details below.
snapshot,webgl Control of mode of display of scene. See Details below.
elementId The id to use on the HTML div component that will hold the scene.
reuse Ignored. See Details below.
webGLoptions A list of options to pass to WebGL when the drawing context is created. See the Details below.
shared An object produced by rglShared, or a list of such objects.
minimal Should attributes be skipped if they currently have no effect? See scene3d.
shinyBrush The name of a Shiny input element to receive information about mouse selections.
oldConvertBBox See Details below.
... Additional arguments to pass to htmlwidgets::createWidget.

Details
This produces a WebGL version of an RGL scene using the htmlwidgets framework. This allows display of the scene in the RStudio IDE, a browser, an rmarkdown document or in a shiny app.

options(rgl.printRglwidget = TRUE) will cause rglwidget() to be called and displayed when the result of an RGL call that changes the scene is printed.

In RMarkdown or in standalone code, you can use a magrittr-style “pipe” command to join an rglwidget with a playwidget or toggleWidget. If the control widget comes first, it should be piped into the controllers argument. If the rglwidget comes first, it can be piped into the first argument of playwidget or toggleWidget.

In earlier versions, the reuse argument let one output scene share data from earlier ones. This is no longer supported.

If elementId is NULL and we are not in a Shiny app, elementId is set to a random value to facilitate re-use of information.

To save the display to a file, use htmlwidgets::saveWidget. This requires pandoc to be installed. For a snapshot, you can use htmltools::save_html(img(src=rglwidget(snapshot=TRUE)),file = ...).

The webGLoptions argument is a list which will be passed when the WebGL context is created. See the WebGL 1.0 specification on https://www.khronos.org/registry/webgl/specs/ for possible settings. The default in rglwidget differs from the WebGL default by setting preserveDrawingBuffer = TRUE in order to allow other tools to read the image, but please note that some implementations of WebGL contain bugs with this setting. We have attempted to work around them, but may change our default in the future if this proves unsatisfactory.

The webgl argument controls whether a dynamic plot is displayed in HTML. In LaTeX and some other formats dynamic plots can’t be displayed, so if the snapshot argument is TRUE, webgl must be FALSE. (In previous versions of the rgl package, both webgl and snapshot could be TRUE; that hasn’t worked for a while and is no longer allowed as of version 0.105.6.)

The snapshot argument controls whether a snapshot is displayed: it must be !webgl if both are specified.
Prior to rgl 0.106.21, `rglwidget` converted bounding box decorations into separate objects: a box, text for the labels, segments for the ticks. By default it now generates these in Javascript, allowing axis labels to move as they do in the display in R. If you prefer the old conversion, set `oldConvertBBox = TRUE`.

**Value**

An object of class "htmlwidget" (or "shiny.tag.list" if pipes are used) that will intelligently print itself into HTML in a variety of contexts including the R console, within R Markdown documents, and within Shiny output bindings.

If objects are passed in the `shared` argument, then the widget will respond to selection and filtering applied to those as shared datasets. See `rglShared` for more details and an example.

**Shiny specifics**

This widget is designed to work with Shiny for interactive displays linked to a server running R.

In a Shiny app, there will often be one or more `playwidget` objects in the app, taking input from the user. In order to be sure that the initial value of the user control is reflected in the scene, you should list all players in the `controllers` argument. See the sample application in `system.file("shinyDemo",package = "rglwidget")` for an example.

In Shiny, it is possible to find out information about mouse selections by specifying the name of an input item in the `shinyBrush` argument. For example, with `shinyBrush = "brush3d"`, each change to the mouse selection will send data to `input$brush3d` in an object of class "rlMouseSelection" with the following components:

- **subscene** The ID of the subscene where the mouse is selecting.
- **state** Either "changing" or "inactive".
- **region** The coordinates of the corners of the selected region in the window, in order `(x1,y1,x2,y2)`.
- **model, proj, view** The model matrix, projection matrix and viewport in effect at that location.

This object can be used as the first argument to `selectionFunction3d` to produce a test function for whether a particular location is in the selected region. If the brush becomes inactive, an object containing only the `state` field will be sent, with value "inactive".

**Appearance**

The appearance of the display is set by the stylesheet in `system.file("htmlwidgets/lib/rglClass/rgl.css")`. The widget is of class `rglWebGL`, with id set according to `elementId`. (As of this writing, no special settings are given for class `rglWebGL`, but you can add your own.)

**Author(s)**

Duncan Murdoch

**See Also**

- `hook_webgl` for an earlier approach to this problem. `rglwidgetOutput` for Shiny details.
Examples

```r
save <- getOption("rgl.useNULL")
options(rgl.useNULL=TRUE)
example("plot3d", "rgl")
widget <- rglwidget()
if (interactive() || in_pkgdown_example())
  widget

if (interactive() && !in_pkgdown_example()) {
  # Save it to a file. This requires pandoc
  filename <- tempfile(fileext = ".html")
  htmlwidgets::saveWidget(rglwidget(), filename)
  browseURL(filename)
}
```

---

**scene**

### Scene management

**Description**

Clear shapes, lights, bbox

**Usage**

```r
clear3d( type = c("shapes", "bboxdeco", "material"), defaults, subscene = 0 )
pop3d( type = "shapes", id = 0, tag = NULL)
ids3d( type = "shapes", subscene = NA, tags = FALSE )
```

**Arguments**

- `type`: Select subtype(s):
  - "shapes" shape stack
  - "lights" light stack
  - "bboxdeco" bounding box
  - "userviewpoint" user viewpoint
  - "modelviewport" model viewpoint
  - "material" material properties
  - "background" scene background
  - "subscene" subscene list
  - "all" all of the above

- `defaults`: default values to use after clearing

- `subscene`: which subscene to work with. NA means the current one, 0 means the whole scene
id vector of ID numbers of items to remove
tag override id with objects matching these tag material properties	
tags logical; whether to return tag column.

Details

RGL holds several lists of objects in each scene. There are lists for shapes, lights, bounding box decorations, subscenes, etc. `clear3d` clears the specified stack, or restores the defaults for the bounding box (not visible) or viewpoint. With `id = 0` `pop3d` removes the last added node on the list (except for subscenes: there it removes the active subscene). The `id` argument may be used to specify arbitrary item(s) to remove; if `id != 0`, the `type` argument is ignored.

`clear3d` may also be used to clear material properties back to their defaults.

`clear3d` has an optional `defaults` argument, which defaults to `r3dDefaults`. Only the `materials` component of this argument is currently used by `clear3d`.

`ids3d` returns a dataframe containing the IDs in the currently active subscene by default, or a specified subscene, or if `subscene = 0`, in the whole `rgl` window along with an indicator of their type and if `tags = TRUE`, the `tag` value for each.

Note that clearing the light stack leaves the scene in darkness; it should normally be followed by a call to `light3d` or `light3d`.

See Also

`rgl`, `bbox3d`, `light3d`, `open3d` to open a new window.

Examples

```r
x <- rnorm(100)
y <- rnorm(100)
z <- rnorm(100)
p <- plot3d(x, y, z, type = 's', tag = "plot")
ids3d()
lines3d(x, y, z)
ids3d(tags = TRUE)
if (interactive() && !rgl.useNULL()) {
  readline("Hit enter to change spheres")
  pop3d(id = p["data"],)
  spheres3d(x, y, z, col = "red", radius = 1/5)
  box3d()
}
```

---

**scene3d**

_Saves the current scene to a variable, and displays such variables_

**Description**

This function saves a large part of the RGL state associated with the current window to a variable.
Usage

scene3d(minimal = TRUE)
## S3 method for class 'rglscene'
plot3d(x, add = FALSE, ...)
## S3 method for class 'rglobject'
plot3d(x, ...)
## S3 method for class 'rglscene'
print(x, ...)
## S3 method for class 'rglobject'
print(x, ...)

Arguments

minimal Should attributes be skipped if they currently have no effect? See Details.
x An object of class "rglscene"
add Whether to open a new window, or add to the existing one.
... Additional parameters, currently ignored.

Details

The components saved are: the par3d settings, the material3d settings, the bg3d settings, the lights and the objects in the scene.

In most cases, calling plot3d on that variable will duplicate the scene. (There are likely to be small differences, mostly internal, but some aspects of the scene are not currently available.) If textures are used, the name of the texture will be saved, rather than the contents of the texture file.

Other than saving the code to recreate a scene, saving the result of scene3d to a file will allow it to be reproduced later most accurately. In roughly decreasing order of fidelity, writeWebGL (now obsolete), writePLY, writeOBJ and writeSTL write the scene to a file in formats readable by other software.

If minimal = TRUE (the default), then attributes of objects will not be saved if they currently have no effect on the display, thereby reducing the file size. Set minimal = FALSE if the scene is intended to be used in a context where the appearance could be changed. Currently this only affects the inclusion of normals; with minimal = TRUE they are omitted for objects when the material is not lit.

Value

The scene3d function returns an object of class "rglscene". This is a list with some or all of the components:

material The results returned from a material3d call.
rootSubscene A list containing information about the main ("root") subscene. This may include:
  id The scene id.
type "subscene"
par3d The par3d settings for the subscene.
embeddings The subsceneInfo()$embeddings for the main subscene.
**objects** The ids for objects in the subscene.

**subscenes** A recursive list of child subscenes.

**objects** A list containing the RGL lights, background and objects in the scene.

The objects in the objects component are of class "rglobject". They are lists containing some or all of the components:

- **id** The RGL identifier of the object in the original scene.
- **type** A character variable identifying the type of object.
- **material** Components of the material that differ from the scene material.
- **vertices, normals, etc.** Any of the attributes of the object retrievable by `rgl.attrib`.
- **ignoreExtent** A logical value indicating whether this object contributes to the bounding box. Currently this may differ from the object in the original scene.

**objects** Sprites may contain other objects; they will be stored here as a list of "rglobject"s.

Lights in the scene are stored similarly, mixed into the objects list.

The `plot3d` methods invisibly return a vector of RGL object ids that were plotted. The `print` methods invisibly return the object that was printed.

**Author(s)**

Duncan Murdoch

**See Also**

`rglwidget`, `writePLY`, `writeOBJ` and `writeSTL` write the scene to a file in various formats.

**Examples**

```r
open3d()
z <- 2 * volcano # Exaggerate the relief
x <- 10 * (1:nrow(z)) # 10 meter spacing (S to N)
y <- 10 * (1:ncol(z)) # 10 meter spacing (E to W)
persp3d(x, y, z, col = "green3", aspect = "iso")

s <- scene3d()
# Make it bigger
s$par3d$windowRect <- 1.5 * s$par3d$windowRect
# and draw it again
plot3d(s)
```
sceneChange

Make large change to a scene from Shiny

Description
These functions allow Shiny apps to make relatively large changes to a scene, adding and removing objects from it.

Usage
sceneChange(elementId, x = scene3d(minimal),
delete = NULL, add = NULL, replace = NULL,
material = FALSE, rootSubscene = FALSE,
delfromSubscenes = NULL, skipRedraw = FALSE,
minimal = TRUE)
registerSceneChange()

Arguments
- **elementId**: The id of the element holding the rglClass instance.
- **x**: The new scene to use as a source for objects to add.
- **delete, add, replace**: Object ids to modify in the scene. The delete and replace ids must be present in the old scene in the browser; the add and replace ids must be present in x.
- **material**: Logical to indicate whether default material should be updated.
- **rootSubscene**: Logical to indicate whether root subscene should be updated.
- **delfromSubscenes**: A vector of subscene ids that may have been changed by deletions. By default, all subscenes in x are used, but the objects may be included in subscenes in the browser that are different.
- **skipRedraw**: If TRUE, stop the scene from redrawing until skipRedraw=FALSE is sent. If NA, don’t redraw this time, but don’t change the state of the skipRedraw flag.
- **minimal**: See scene3d.

Details
registerSceneChange must be called in the UI component of a Shiny app to register the “sceneChange” custom message.

Value
registerSceneChange returns the HTML code to register the message.
sceneChange returns a list to be used as the “sceneChange” message to change the scene. Use shiny::session$sendCustomMessage to send it.
select3d

Select a rectangle in an RGL scene

Description

This function allows the user to use the mouse to select a region in an RGL scene.

Usage

rgl.select3d(button = c("left", "middle", "right"),
              dev = cur3d(),
              subscene = currentSubscene3d(dev))

select3d(...)

selectionFunction3d(proj, region = proj$region)

Arguments

button Which button to use for selection.
dev, subscene The RGL device and subscene to work with
... Button argument to pass to rgl.select3d
proj An object returned from rgl.projection containing details of the current projection.
region Corners of a rectangular region in the display.
select3d and rgl.select3d select 3-dimensional regions by allowing the user to use a mouse to draw a rectangle showing the projection of the region onto the screen. They return a function which tests points for inclusion in the selected region.

selectionFunction3d constructs such a test function given coordinates and current transformation matrices.

If the scene is later moved or rotated, the selected region will remain the same, though no longer corresponding to a rectangle on the screen.

Value

All of these return a function \( f(x, y, z) \) which tests whether each of the points \((x, y, z)\) is in the selected region, returning a logical vector. This function accepts input in a wide variety of formats as it uses \texttt{xyz.coords} to interpret its parameters.

Ming Chen / Duncan Murdoch

See Also

selectpoints3d, locator

Examples

# Allow the user to select some points, and then redraw them # in a different color
if (interactive()) {
  x <- rnorm(1000)
y <- rnorm(1000)
z <- rnorm(1000)
open3d()
points3d(x, y, z)
f <- select3d()
if (!is.null(f)) {
  keep <- f(x, y, z)
  pop3d()
  points3d(x[keep], y[keep], z[keep], color = 'red')
  points3d(x[!keep], y[!keep], z[!keep])
}
}
selectpoints3d

Select points from a scene

Description

This function uses the select3d function to allow the user to choose a point or region in the scene, then reports on all the vertices in or near that selection.

Usage

```r
selectpoints3d(objects = ids3d()$id, value = TRUE, closest = TRUE,
multiple = FALSE, ...)
```

Arguments

- `objects` A vector of object id values to use for the search.
- `value` If `TRUE`, return the coordinates of the points; otherwise, return their indices.
- `closest` If `TRUE`, return the points closest to the selection of no points are exactly within it.
- `multiple` If `TRUE` or a function, do multiple selections. See the Details below.
- `...` Other parameters to pass to `select3d`.

Details

The `multiple` argument may be a logical value or a function. If logical, it controls whether multiple selections will be performed. If `multiple` is `FALSE`, a single selection will be performed; it might contain multiple points. If `TRUE`, multiple selections will occur and the results will be combined into a single matrix.

If `multiple` is a function, it should take a single argument. This function will be called with the argument set to a matrix containing newly added rows to the value, i.e. it will contain coordinates of the newly selected points (if `value = TRUE`), or the indices of the points (if `value = FALSE`). It should return a logical value, `TRUE` to indicate that selection should continue, `FALSE` to indicate that it should stop.

In either case, if multiple selections are being performed, the ESC key will stop the process.

Value

If `value` is `TRUE`, a 3-column matrix giving the coordinates of the selected points. All rows in the matrix will be unique even if multiple vertices have the same coordinates.

If `value` is `FALSE`, a 2-column matrix containing columns:

- `id` The object id containing the point.
- `index` The index of the point within `rgl.attrib(id,"vertices")`. If multiple points have the same coordinates, all indices will be returned.
**Author(s)**

Duncan Murdoch

**See Also**

`select3d` to return a selection function.

**Examples**

```r
xyz <- cbind(rnorm(20), rnorm(20), rnorm(20))
ids <- plot3d( xyz )

if (interactive()) {
  # Click near a point to select it and put a sphere there.
  # Press ESC to quit...

  # This version returns coordinates
  selectpoints3d(ids["data"],
    multiple = function(x) {
      spheres3d(x, color = "red", alpha = 0.3, radius = 0.2)
      TRUE
    })

  # This one returns indices
  selectpoints3d(ids["data"], value = FALSE,
    multiple = function(ids) {
      spheres3d(xyz[ids[, "index"], , drop = FALSE], color = "blue",
        alpha = 0.3, radius = 0.2)
      TRUE
    })
}
```

---

**setAxisCallbacks**

User-defined axis labelling callbacks.

**Description**

This function sets user callbacks to construct axes in R or `rglwidget` displays.

**Usage**

```r
setAxisCallbacks(axes, fns,
  javascript = NULL,
  subscene = scene$rootSubscene$id,
  scene = scene3d(minimal = FALSE),
  applyToScene = TRUE,
  applyToDev = missing(scene))
```
Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>axes</td>
<td>Which axes? Specify as number in 1:3 or letter in c(&quot;x&quot;,&quot;y&quot;,&quot;z&quot;).</td>
</tr>
<tr>
<td>fns</td>
<td>Function or list of functions or character vector giving names of functions.</td>
</tr>
<tr>
<td>javascript</td>
<td>Optional block of Javascript code to be included (at the global level).</td>
</tr>
<tr>
<td>subscene</td>
<td>Which subscene do these callbacks apply to?</td>
</tr>
<tr>
<td>scene</td>
<td>Which scene?</td>
</tr>
<tr>
<td>applyToScene</td>
<td>Should these changes apply to the scene object?</td>
</tr>
<tr>
<td>applyToDev</td>
<td>Should these changes apply to the current device?</td>
</tr>
</tbody>
</table>

Details

If applyToScene is TRUE, this function adds Javascript callbacks to the scene object. If applyToDev is TRUE, it adds R callbacks to the current RGL device.

For Javascript, the callbacks are specified as strings; these will be evaluated within the browser in the global context to define the functions, which will then be called with the Javascript this object set to the current rglwidgetClass object.

For R, they may be strings or R functions.

Both options may be TRUE, in which case the callbacks must be specified as strings which are both valid Javascript and valid R. The usual way to do this is to give just a function name, with the function defined elsewhere, as in the Example below.

The functions should have a header of the form function(margin). The margin argument will be a string like "x++" indicating which margin would be chosen by R. If RGL would not choose to draw any axis annotations (which happens with rglwidget, though not currently in R itself), only the letter will be passed, e.g. "x".

Value

Invisibly returns an rglScene object. This object will record the changes if applyToScene is TRUE. If applyToDev is TRUE, it will also have the side effect of attempting to install the callbacks using rgl.setAxisCallback.

Author(s)

Duncan Murdoch

setUserCallbacks for mouse callbacks.

Examples

# Draw arrows instead of tick marks on axes

```r
arrowAxis <- local{
  ids <- c(NA, NA, NA)
  bbox <- c(NA, NA, NA, NA, NA, NA)
}
```
function(margin) {
  dim <- if (grepl("x", margin)) 1 else
    if (grepl("y", margin)) 2 else
      3
  ind <- 2*dim + (-1):0
  range <- par3d("bbox")[inds]
  if (!identical(bbox[inds], range)) {
    if (!is.na(ids[dim]))
      pop3d(id = ids[dim])
    bbox[inds] <<- range
    center <- mean(range)
    from <- mean(c(range[1], center))
    to <- mean(c(center, range[2]))
    # margin should agree with suggestion, so use "x++" etc.
    margin <- gsub("-", "+-", margin)
    ids[dim] <<- arrow3d(p0 = c(from, 1, 1),
                        p1 = c(to, 1, 1),
                        n = 4,
                        type = "lines",
                        margin = margin,
                        floating = TRUE)
  }
}
}

# Define the Javascript function with the same name to use in WebGL
# Since Javascript won't change the bounding box, this function
# doesn't need to do anything.
js <- "
window.arrowAxis = function(margin) {} ;
"

xyz <- matrix(rnorm(60), ncol = 3)
plot3d(xyz, xlab = "x", ylab = "y", zlab = "z")
setAxisCallbacks(1:3, "arrowAxis", javascript = js)
rglwidget()

desc

setGraphicsDelay

**Set a one-time slowdown on opening standard graphics**

**Description**

This function is mainly for internal use, to work around a bug in macOS Catalina: if base plotting happens too quickly after opening RGL and the first call to quartz, R crashes.

This inserts a delay after the first call to open the graphics device. The default is no delay, unless on Catalina with no graphics device currently open but the quartz device set as the default, when a 1 second delay will be added. Use environment variable "RGL_SLOW_DEV = value" to set a different default delay.
It works by changing the value of `options("device")`, so explicit calls to the device will not be affected.

It is called automatically when the `rgl` package is loaded.

**Usage**

```r
setGraphicsDelay(delay = Sys.getenv("RGL_SLOW_DEV", 0),
unixos = "none")
```

**Arguments**

- **delay**: Number of seconds for the delay.
- **unixos**: The name of the Unix OS. If set to "Darwin", and the version is 19.0.0 or greater, the default delay is changed to 1 second.

**Value**

Called for the side effect of adding the delay to the first opening of the graphics device.

---

**Description**

These functions allow RGL graphics to be embedded in `knitr` documents. The simplest method is to run `setupKnitr(autoprint = TRUE)` early in the document. That way RGL commands act a lot like base graphics commands: plots will be automatically inserted where appropriate, according to the `fig.keep` chunk option. By default (`fig.keep = "high"`), only high-level plots are kept, after low-level changes have been merged into them. See the `knitr` documentation [https://yihui.org/knitr/options/#plots](https://yihui.org/knitr/options/#plots) for more details. To suppress auto-printing, the RGL calls can be wrapped in `invisible()`. Similarly to `grid` graphics (used by `lattice` and `ggplot2`), automatic inclusion requires the object to be printed: only the last statement in a code block in braces is automatically printed. Unlike those packages, auto-printing is the only way to get this to work: calling `print` explicitly doesn’t work.

Other functions allow embedding either as bitmaps (`hook_rgl` with format "png"), fixed vector graphics (`hook_rgl` with format "eps", "pdf" or "postscript"), or interactive WebGL graphics (`hook_webgl`). `hook_rglchunk` is not normally invoked by the user; it is the hook that supports automatic creation and deletion of RGL scenes.

**Usage**

```r
setupKnitr(autoprint = FALSE,
    rgl.newwindow = autoprint,
    rgl.closewindows = autoprint)
hook_rgl(before, options, envir)
hook_webgl(before, options, envir)
hook_rglchunk(before, options, envir)
```
Arguments

- **autoprint**: If true, RGL commands automatically plot (with low level plots suppressed by the default value of the `fig.keep` chunk option.)
- **rgl.newwindow**, **rgl.closewindows**: Default values for the **knitr** chunk options.
- **before**, **options**, **envir**: Standard **knitr** hook function arguments.

Details

The `setupKnitr()` function needs to be called once at the start of the document to install the **knitr** hooks. If it is called twice in the same session the second call will override the first.

The following chunk options are supported:

- **rgl.newwindow**: Whether to open a new window for the chunk. Default is set by `setupKnitr` argument.
- **rgl.closewindows**: Whether to close windows at the end of the chunk. Default is set by `setupKnitr` argument.
- **rgl.margin** (default 100): number of pixels by which to indent the WebGL window.
- **snapshot**: Logical value: when autoprinting in HTML, should a snapshot be used instead of the dynamic WebGL display? Corresponds to `rglwidget(snapshot = TRUE, webgl = FALSE)`. Ignored in LaTeX, where a snapshot will always be produced (unless `fig.keep` specifies no figure at all).
- **dpi**, **fig.retina**, **fig.width**, **fig.height**: standard **knitr** chunk options used to set the size of the output.
- **fig.keep**, **fig.hold**, **fig.beforecode**: standard **knitr** chunk options used to control the display of plots.
- **dev**: used by hook_rgl to set the output format. May be “eps”, "postscript", "pdf" or "png" (default: "png").
- **rgl.keepopen**: no longer used. Ignored with a warning.

Value

A string to be embedded into the output, or **NULL** if called when no output is available.

Note

The `setupKnitr(autoprint = TRUE)` method assumes all printing of RGL objects happens through auto-printing of objects produced by the **lowlevel** or **highlevel** functions. All RGL functions that produce graphics do this, but functions in other packages that call them may not return values appropriately.

If you have multiple calls to `setupKnitr()`, all should have the same arguments. If any differ, a warning will be issued, and the first set of arguments will be used.

Mixing explicit calls to `rglwidget` with auto-printing is likely to lead to failure of some scenes to display. To avoid this, set `options(rgl.printRglwidget = FALSE)` before using such explicit calls. Similarly, use that option before calling the **example** function in a code chunk if the example prints RGL objects.
**Author(s)**

The hook* functions are originally by Yihui Xie in the `knitr` package; and have been modified by Duncan Murdoch. Some parts of the `setupKnitr` function duplicate source code from `knitr`.

---

**setUserCallbacks**

*Set mouse callbacks in R or Javascript code*

**Description**

This function sets user mouse callbacks in R or `rglwidget` displays.

**Usage**

```r
def setUserCallbacks(button, 
    begin = NULL, 
    update = NULL, 
    end = NULL, 
    rotate = NULL, 
    javascript = NULL, 
    subscene = scene$rootSubscene$id, 
    scene = scene3d(minimal = FALSE), 
    applyToScene = TRUE, 
    applyToDev = missing(scene))
```

**Arguments**

- `button`: Which button should this callback apply to? Can be numeric from 0:4, or character from "none", "left", "right", "center", "wheel".
- `begin`, `update`, `end`, `rotate`: Functions to call when events occur. See Details.
- `javascript`: Optional block of Javascript code to be included (at the global level).
- `subscene`: Which subscene do these callbacks apply to?
- `scene`: Which scene?
- `applyToScene`: Should these changes apply to the scene object?
- `applyToDev`: Should these changes apply to the current device?

**Details**

If `applyToScene` is TRUE, this function adds Javascript callbacks to the scene object. If `applyToDev` is TRUE, it adds R callbacks to the current RGL device.

For Javascript, the callbacks are specified as strings; these will be evaluated within the browser in the global context to define the functions, which will then be called with the Javascript `this` object set to the current `rglwidgetClass` object.

For R, they may be strings or R functions.
Both options may be TRUE, in which case the callbacks must be specified as strings which are both valid Javascript and valid R. The usual way to do this is to give just a function name, with the function defined elsewhere, as in the Example below.

The begin and update functions should be of the form function(x, y) { ... }. The end function will be called with no arguments.

The rotate callback can only be set on the mouse wheel. It is called when the mouse wheel is rotated. It should be of the form function(away), where away will be 1 while rotating the wheel “away” from you, and 2 while rotating it towards you. If rotate is not set but other callbacks are set on the wheel “button”, then each click of the mouse wheel will trigger all start, update, then end calls in sequence.

The javascript argument is an optional block of code which will be evaluated once during the initialization of the widget. It can define functions and assign them as members of the window object, and then the names of those functions can be given in the callback arguments; this allows the callbacks to share information.

Value

Invisibly returns an rglScene object. This object will record the changes if applyToScene is TRUE. If applyToDev is TRUE, it will also have the side effect of attempting to install the callbacks using rgl.setMouseCallbacks and rgl.setWheelCallback.

  text.colors[0][3] = 1; // alpha is here!
  text.texts[0] = (closest + 1).toString();
  text.initialized = false;
  this.drawScene();
setUserShaders

Set user-defined shaders for RGL objects.

Description

Sets user-defined shaders (programs written in GLSL) for customized display of RGL objects. Currently only supported in WebGL displays, as the regular displays do not support GLSL.

Usage

setUserShaders(ids, vertexShader = NULL, fragmentShader = NULL,
               attributes = NULL, uniforms = NULL,
               scene = scene3d(minimal), minimal = TRUE)

Arguments

ids        Which objects should receive the shaders.
vertexShader, fragmentShader
            The vertex and fragment shader source code. If NULL, the automatically generated shader will be used instead.
attributes     A named list of “attributes” to attach to each vertex.
unforms     A named list of “uniforms”.
scene        A scene3d object to modify.
minimal     See scene3d.
Details

Modern versions of OpenGL work with “shaders”, programs written to run on the graphics processor. The vertex shader does the calculations to move vertices and set their intrinsic colours. The fragment shader computes how each pixel in the display will be shown, taking into account lighting, material properties, etc. (More precisely, it does the computation for each “fragment”; a fragment is a pixel within an object to display. There may be many objects at a particular location, and each will result in a fragment calculation unless culled by z-buffering or being discarded in some other way.)

Normally the WebGL code automatically generates shaders for each object. This function allows them to be written by hand, for testing new features, hand optimization, etc. Currently it is not easy to get copies of the default shaders; they need to be obtained from a Javascript debugger while displaying the scene.

Value

A modified version of the scene.

draw3d

**Description**

Draws 3D mesh objects in full, or just the edges, or just the vertices.

**Usage**

```r
dot3d(x, ...) # draw dots at the vertices of an object
## S3 method for class 'mesh3d'
dot3d(x, ...,
  front = "points", back = "points")
wire3d(x, ...) # draw a wireframe object
## S3 method for class 'mesh3d'
wire3d(x, ...,
  front = "lines", back = "lines")
shade3d(x, ...) # draw a shaded object
## S3 method for class 'mesh3d'
shade3d(x, override = TRUE,
  meshColor = c("vertices", "edges", "faces", "legacy"),
  texcoords = NULL, ...,
  front = "filled", back = "filled")
```

**Arguments**

- `x`: a `mesh3d` object.
- `...`: additional rendering parameters, or for dots3d and wire3d, parameters to pass to shade3d
- `override`: should the parameters specified here override those stored in the object?
- `meshColor`: how should colours be interpreted? See details below
- `texcoords`: texture coordinates at each vertex.
- `front, back`: Material properties for rendering.

**Details**

The `meshColor` argument controls how material colours and textures are interpreted. This parameter was added in `rgl` version 0.100.1 (0.100.27 for dot3d). Possible values are:

- "vertices": Colours and texture coordinates are applied by vertex, in the order they appear in the `x$vb` matrix.
"edges" Colours are applied to each edge: first to the segments in the $x$s matrix, then the 3 edges of each triangle in the $x$it matrix, then the 4 edges of each quad in the $x$ib matrix. This mode is only supported if both front and back materials are "lines", and the mesh contains no points.

"faces" Colours are applied to each face: first to the triangles in the it matrix, then to the quads in the ib matrix. Not compatible with meshes containing points or segments.

"legacy" Colours and textures are applied in the same way as in rgl versions earlier than 0.100.1.

Unique partial matches of these values will be recognized.

If colours are specified but meshColor is not and options(rgl.meshColorWarning = TRUE), a warning will be given that their interpretation may have changed. In versions 0.100.1 to 0.100.26 of rgl, the default was to give the warning; now the default is for no warning.

Note that since version 0.102.10, meshColor = "edges" is only allowed when drawing lines (the wire3d default), and it may draw edges more than once. In general, if any rendering draws twice at the same location, which copy is visible depends on the order of drawing and the material3d("depth_test") setting.

Whether points, lines or solid faces are drawn is determined in 3 steps:

1. If arguments "front" or "back" are specified in the call, those are used.
2. If one or both of those arguments are not specified, but the material properties are present in the object, those are used.
3. If values are not specified in either of those places, shade3d draws filled surfaces, wire3d draws lines, and dot3d draws points.

Note: For some versions of rgl up to version 0.107.15, rule 2 above was not respected.

Value
dot3d, wire3d, and shade3d are called for their side effect of drawing an object into the scene; they return an object ID (or vector of IDs) invisibly.

See rgl.primitive for a discussion of texture coordinates.

shade3d( translate3d( icosahedron3d(col = "magenta"), 12, 0, 0 ) )

shadow3d

Project shadows of mesh onto object.

Description

Project a mesh onto a surface in a scene so that it appears to cast a shadow onto the surface.

Usage

shadow3d(obj, mesh, plot = TRUE, up = c(0, 0, 1),
    P = projectDown(up), outside = FALSE,
    ...)

Arguments

obj
mesh
plot
up
P
outside
...

Other arguments to pass to filledContour3d, which will do the boundary calculations and plotting.
Details

shadow3d internally constructs a function that is zero on the boundary of the shadow and positive inside, then draws filled contours of that function. Because the function is nonlinear, the boundaries will be approximate, with the best approximation resulting from a large value of `filledContour3d` parameter `minVertices`.

If `outside = TRUE`, the first color used by `filledContour3d` will indicate the inside of the shadow, and the second color will indicate the exterior.

Value

The returned value from `filledContour3d`.

drape3d, facing3d

Examples

```r
open3d()
obj <- translate3d(scale3d(oh3d(), 0.3, 0.3, 0.3), 0,0,2)
shade3d(obj, col = "red")
target <- icosahedron3d()

# We offset the target using polygon_offset = 1 so that the
# shadow on its surface will appear clearly.
shade3d(target, col = "white", polygon_offset = 1)

# minVertices = 1000 leaves noticeable artifacts on the edges
# of the shadow. A larger value gives a better result, but is
# slower.

# We use facing3d(target) so the shadow and outside part only
# appear on the upper side of the target
shadow3d(facing3d(target), obj, minVertices = 1000, plot=TRUE,
          col = c("yellow", "blue"), outside = TRUE)
```

shapelist3d

Create and plot a list of shapes

Description

These functions create and plot a list of shapes.
shapelist3d

Usage

shapelist3d(shapes, x = 0, y = NULL, z = NULL, size = 1, matrix = NULL, override = TRUE, ...
..., plot = TRUE)

Arguments

shapes A single shape3d object, or a list of them.
x, y, z Translation(s) to apply
size Scaling(s) to apply
matrix A single matrix transformation, or a list of them.
override Whether the material properties should override the ones in the shapes.
... Material properties to apply.
plot Whether to plot the result.

Details

shapelist3d is a quick way to create a complex object made up of simpler ones. Each of the arguments shapes through override may be a vector of values (a list in the case of shapes or matrix). All values will be recycled to produce a list of shapes as long as the longest of them.

The xyz.coords function will be used to process the x, y and z arguments, so a matrix may be used as x to specify all three. If a vector is used for x but y or z is missing, default values of 0 will be used.

The "shapelist3d" class is simply a list of "shape3d" objects.

Methods for dot3d, wire3d, shade3d, translate3d, scale3d, and rotate3d are defined for these objects.

Value

An object of class c("shapelist3d","shape3d").

shiny  

Functions for integration of RGL widgets into Shiny app

Description

These functions allow an RGL scene to be embedded in a Shiny app.

Usage

rglwidgetOutput(outputId, width = "512px", height = "512px")
renderRglwidget(expr, env = parent.frame(), quoted = FALSE, outputArgs = list())

playwidgetOutput(outputId, width = "0px", height = "0px")
renderPlaywidget(expr, env = parent.frame(), quoted = FALSE, outputArgs = list())

Arguments

outputId  The name for the control.
width, height  Width and height to display the control.
expr  An R expression returning a rglwidget (for renderRglwidget) or a playwidget (for renderPlaywidget) as output.
env  The environment in which to evaluate expr.
quoted  Is the expression already quoted?
outputArgs  A list containing arguments; see details below.

Details

Use rglwidgetOutput or playwidgetOutput as an output object in a Shiny user interface section; use renderRglwidget or renderPlaywidget as the render function in the server section.

In a dynamic R Markdown document with runtime: shiny, you only call the render function, and may optionally pass width and height to the output function by putting them in a list in outputArgs. See the example below.

Value

Used internally by Shiny.

Author(s)

Duncan Murdoch
shinyGetPar3d

Communicate RGL parameters between R and Javascript in Shiny

Description

These functions allow Shiny apps to read and write the par3d settings that may have been modified by user interaction in the browser.

Usage

shinyGetPar3d(parameters, session, subscene = currentSubscene3d(cur3d()), tag = "")
shinySetPar3d(..., session, subscene = currentSubscene3d(cur3d()))
shinyResetBrush(session, brush)

Arguments

- **parameters** A character vector naming the parameters to get.
- **session** The Shiny session object.
- **subscene** The subscene to which the parameters apply. Defaults to the currently active subscene in the R session.
- **tag** An arbitrary string or value which will be sent as part of the response.
- **...** A number of name = value pairs to be modified, or a single named list of parameters. Entries named tag or subscene will be ignored.
- **brush** The name of a Shiny input element corresponding to the shinyBrush argument to rglwidget.
Details

Requesting information from the browser is a complicated process. The `shinyGetPar3d` function doesn't return the requested value, it just submits a request for the value to be returned later in `input$par3d`, a reactive input. No action will result except when a reactive observer depends on `input$par3d`. See the example code below.

The `shinySetPar3d` function sends a message to the browser asking it to change a particular parameter. The change will be made immediately, without sending the full scene to the browser, so should be reasonably fast.

Value

These functions are called for their side effects, and don’t return useful values.

The side effect of `shinyGetPar3d` is to cause `input$par3d` to be updated sometime later. Besides the requested parameter values, `input$par3d` will contain a copy of the subscene and tag arguments.

The side effect of `shinySetPar3d` is to send a message to the browser to update its copy of the `par3d` parameters immediately.

Note

R and the browser don't maintain a perfect match between the way parameters are stored internally. The browser version of parameters will be returned by `shinyGetPar3d` and should be supplied to `shinySetPar3d`.

The `rglwidget` argument `shinySelectionInput` allows information about mouse selections to be returned to R.

Examples

```r
if (interactive() && !in_p gdow_example() && requireNamespace("shiny")) {
  save <- options(rgl.useNULL = TRUE)

  xyz <- matrix(rnorm(300), ncol = 3)

  app <- shiny::shinyApp(
    ui = shiny::bootstrapPage(
      shiny::actionButton("redraw", "Redraw"),
      rglwidgetOutput("rglPlot"))
  )
```
show2d

Draw a 2D plot on a rectangle in a 3D scene

Description

This function uses a bitmap of a standard 2D graphics plot as a texture on a quadrilateral. Default arguments are set up so that it will appear on the face of the bounding box of the current 3D plot, but optional arguments allow it to be placed anywhere in the scene.

Usage

```r
show2d(expression,
       face = "z-", line = 0,
       reverse = FALSE, rotate = 0,
       x = NULL, y = NULL, z = NULL,
       width = 480, height = 480,
       filename = NULL,
       ignoreExtent = TRUE,
       color = "white", specular = "black", lit = FALSE,
       texmipmap = TRUE, texminfilter = "linear.mipmap.linear",
       expand = 1.03,
       texcoords = matrix(c(0, 1, 1, 0, 0, 0, 1, 1), ncol = 2), 
                      ...)```
```
Arguments

expression    Any plotting commands to produce a plot in standard graphics. Ignored if filename is not NULL.
face          A character string defining which face of the bounding box to use. See Details below.
line          How far out from the bounding box should the quadrilateral be placed? Uses same convention as mtext3d: not lines of text, but fraction of the bounding box size.
reverse, rotate Should the image be reversed or rotated? See Details below.
x, y, z        Specific values to use to override face.
width, height  Parameters to pass to png when creating the bitmap. See Details below.
filename      A ‘.png’ file image to use as the texture.
ignoreExtent  Whether the quadrilateral should be ignored when computing the bounding box of the scene.
color, specular, lit, texmipmap, texminfilter, ... Material properties to use for the quadrilateral.
expand        Amount by which the quadrilateral is expanded outside the bounding box of the data.
texcoords     Coordinates on the image. Lower left of the bitmap is c(0,0), upper right is c(1,1).

Details

The default arguments are chosen to make it easy to place a 2D image on the face of the bounding box. If x, y and z are NULL (the defaults), face will be used as a code for one of the six faces of the bounding box. The first letter should be "x", "y" or "z"; this defines the axis perpendicular to the desired face. If the second letter is "-" or is missing, the face will be chosen to be the face with the lower value on that axis. Any other letter will use the opposite face.

If any of x, y or z is given, the specified value will be used to replace the value calculated above. Usually four values should be given, corresponding to the coordinates of the lower left, lower right, upper right and upper left of the destination for the image before reverse and rotate are used. Fewer values can be used for one or two coordinates; cbind will be used to put together all 3 coordinates into a 4 by 3 matrix (which will be returned as an attribute of the result).

The bitmap plot will by default be oriented so that it is properly oriented when viewed from the direction of the higher values of the perpendicular coordinate, and its lower left corner is at the lower value of the two remaining coordinates. The argument reverse causes the orientation to be mirrored, and rotate causes it to be rotated by multiples of 90 degrees. rotate should be an integer, with 0 for no rotation, 1 for a 90 degree counter-clockwise rotation, etc.

The width and height arguments control the shape and resolution of the bitmap. The defaults give a square bitmap, which is appropriate with the usual c(1,1,1) aspect ratios (see aspect3d). Some tuning may be needed to choose the resolution. The plot will look best when displayed at its original size; shrinking it smaller tends to make it look faded, while expanding it bigger will make it look blurry. If filename is given, the width and height will be taken from the file, and width and height arguments will be ignored.
**Value**

Invisibly returns the id value of the quadrilateral, with the following attributes:

- **value**: The value returned by expression.
- **xyz**: A 4 by 3 matrix giving the coordinates of the corners as used in plotting.
- **texcoords**: A 4 by 2 matrix giving the texture coordinates of the image.
- **filename**: The filename for the temporary file holding the bitmap image.

**Author(s)**

Duncan Murdoch

**See Also**

- `bgplot3d` uses a plot as the background for the window.

**Examples**

```r
example(plot3d, ask = FALSE)
show2d(
  par(mar=c(0,0,0,0))
  plot(x, y, col = rainbow(1000), axes=FALSE)
)
```

**Description**

Saves the screenshot to a file.

**Usage**

```r
rgl.snapshot( filename, fmt = "png", top = TRUE )
snapshot3d( filename = tempfile(fileext = ".png"),
  fmt = "png", top = TRUE,
  ..., scene, width = NULL, height = NULL,
  webshot = TRUE)
```

**Arguments**

- **filename**: path to file to save.
- **fmt**: image export format, currently supported: png. Ignored if webshot = TRUE.
- **top**: whether to call `rgl.bringtotop`. Ignored if webshot = TRUE.
- **scene**: arguments to pass to `webshot2::webshot`
- **width, height**: optional specifications of output size in pixels
- **webshot**: Use the `webshot2` package to take the snapshot
Details

`rgl.snapshot()` is a low-level function that copies the current RGL window from the screen. Users should use `snapshot3d()` instead; it is more flexible, and (if `webshot2` is installed) can take images even if no window is showing, and they can be larger than the physical screen.

Animations can be created in a loop modifying the scene and saving each screenshot to a file. Various graphics programs (e.g. ImageMagick) can put these together into a single animation. (See `movie3d` or the example below.)

Value

These functions are mainly called for the side effects. The filename of the saved file is returned invisibly.

Note

When `rgl.useNULL()` is `TRUE`, only `webshot = TRUE` will produce a snapshot. It requires the `webshot2` package, which as of this writing is not available on CRAN; to install it, use `remotes::install_github("rstudio/webshot2")`

`rgl.snapshot` works by taking an image from the displayed window on-screen. On some systems, the snapshot will include content from other windows if they cover the active RGL window. Setting `top = TRUE` (the default) will use `rgl.bringtotop` before the snapshot to avoid this.

There are likely limits to how large `width` and `height` can be set based on the display hardware; if these are exceeded the results are undefined. A typical result is that the snapshot will still be made but at a smaller size.

There are slight differences between the displays with `webshot = TRUE` and `webshot = FALSE`, as the former are rendered using WebGL while the latter are rendered using OpenGL. Often the `webshot = TRUE` displays have better quality.

Examples

```r
if (interactive() && !in_pkgdown_example()) {
  saveopts <- options(rgl.useNULL = TRUE)
  plot3d(matrix(rnorm(300), ncol = 3, dimnames = list(NULL, c("x", "y", "z"))),
         col = "red")
  options(saveopts)
  browseURL(snapshot3d())
}
```

## Not run:

#
# create animation
#

`shade3d(oh3d(), color = "red")`

`rgl.bringtotop()`
spheres3d

Add spheres

Description

Adds a sphere set shape node to the scene

Usage

spheres3d(x, y = NULL, z = NULL, radius = 1, fastTransparency = TRUE, ...)

Arguments

x, y, z Numeric vector of point coordinates corresponding to the center of each sphere. Any reasonable way of defining the coordinates is acceptable. See the function `xyz.coords` for details.

radius Vector or single value defining the sphere radius/radii

fastTransparency logical value indicating whether fast sorting should be used for transparency. See the Details.

... Material properties. See `material3d` for details.

Details

If a non-isometric aspect ratio is chosen, these functions will still draw objects that appear to the viewer to be spheres. Use `ellipse3d` to draw shapes that are spherical in the data scale.

When the scale is not isometric, the radius is measured in an average scale. In this case the bounding box calculation is iterative, since rescaling the plot changes the shape of the spheres in user-coordinates, which changes the bounding box. Versions of `rgl` prior to 0.92.802 did not do this iterative adjustment.

If any coordinate or radius is `NA`, the sphere is not plotted.
If a texture is used, its bitmap is wrapped around the sphere, with the top edge at the maximum y coordinate, and the left-right edges joined at the maximum in the z coordinate, centred in x.

If the alpha material value of the spheres is less than the default 1, they need to be drawn in order from back to front. When fastTransparency is TRUE, this is approximated by sorting the centers and drawing complete spheres in that order. This produces acceptable results in most cases, but artifacts may be visible, especially if the radius values vary, or they intersect other transparent objects. Setting fastTransparency = FALSE will cause the sorting to apply to each of the 480 facets of individual spheres. This is much slower, but may produce better output.

Value

A shape ID of the spheres object is returned.

See Also

material3d, aspect3d for setting non-isometric scales

Examples

open3d()

spheres3d(rnorm(10), rnorm(10), rnorm(10),
    radius = runif(10), color = rainbow(10))

spin3d

Create a function to spin a scene at a fixed rate

Description

This creates a function to use with play3d to spin an RGL scene at a fixed rate.

Usage

spin3d(axis = c(0, 0, 1), rpm = 5,
    dev = cur3d(), subscene = par3d("listeners", dev = dev))

Arguments

axis The desired axis of rotation
rpm The rotation speed in rotations per minute
dev Which RGL device to use
subscene Which subscene to use

Value

A function with header function(time, base = M), where M is the result of par3d("userMatrix") at the time the function is created. This function calculates and returns a list containing userMatrix updated by spinning the base matrix for time seconds at rpm revolutions per minute about the specified axis.
**Note**

Prior to **rgl** version 0.95.1476, the subscene argument defaulted to the current subscene, and any additional entries would be ignored by **play3d**. The current default value of `par3d("listeners", dev = dev)` means that all subscenes that share mouse responses will also share modifications by this function.

**Author(s)**

Duncan Murdoch

**See Also**

**play3d** to play the animation

**Examples**

```r
# Spin one object
open3d()
plot3d(oh3d(col = "lightblue", alpha = 0.5))
if (!rgl.useNULL())
  play3d(spin3d(axis = c(1, 0, 0), rpm = 30), duration = 2)

# Show spinning sprites, and rotate the whole view
open3d()
spriteid <- NULL
spin1 <- spin3d(rpm = 4.5 ) # the scene spinner
spin2 <- spin3d(rpm = 9 ) # the sprite spinner
f <- function(time) {
  par3d(skipRedraw = TRUE) # stops intermediate redraws
  on.exit(par3d(skipRedraw = FALSE)) # redraw at the end

  pop3d(id = spriteid) # delete the old sprite
  cubeid <- shade3d(cube3d(), col = "red")
  spriteid <<- sprites3d(0:1, 0:1, 0:1, shape = cubeid,
    userMatrix = spin2(time,
      base = spin1(time)$userMatrix)$userMatrix)
  spin1(time)
}
if (!rgl.useNULL())
  play3d(f, duration = 2)
```

---

**sprites**

*Add sprites*

**Description**

Adds a sprite set shape node to the scene.
Usage

```r
sprites3d(x = NULL, y = NULL, z = NULL, radius = 1,
    shapes = NULL, userMatrix = NULL,
    fixedSize = FALSE,
    adj = 0.5, pos = NULL, offset = 0.25, ...)
particles3d(x, y = NULL, z = NULL, radius = 1, ...)
```

Arguments

- `x, y, z` point coordinates. Any reasonable way of defining the coordinates is acceptable. See the function `xyz.coords` for details.
- `radius` vector or single value defining the sprite radius
- `shapes` NULL for a simple square, or a vector of identifiers of shapes in the scene
- `userMatrix` if `shapes` is not NULL, the transformation matrix for the shapes
- `fixedSize` should sprites remain at a fixed size, or resize with the scene?
- `adj, pos, offset` positioning arguments; see Details
- `...` material properties when `shapes = NULL, texture mapping is supported`

Details

Simple sprites (used when `shapes` is NULL) are 1 by 1 squares that are directed towards the viewpoint. Their primary use is for fast (and faked) atmospherical effects, e.g. particles and clouds using alpha blended textures. Particles are sprites using an alpha-blended particle texture giving the illusion of clouds and gases. The centre of each square will by default be at the coordinates given by `x, y, z`. This may be adjusted using the `adj` or `pos` parameters.

`adj` and `pos` are treated similarly to the same parameters for `text3d`. `adj` has 3 entries, for adjustment to the `x`, `y` and `z` coordinates respectively. For `x`, a value of 0 puts the sprite to the right of the specified point, 0.5 centers it there, and 1 puts it to the left. The other coordinates are similar. By default, each value is 0.5 and the sprites are centered at the points given by `(x, y, z)`.

The `pos` parameter overrides `adj`. It should be an integer or vector of integers (one per point), interpreted as in `text3d` to position the sprite relative to the `(x, y, z)` point: 0 is centered on it, 1 is below, 2 is to the left, 3 is above, 4 is to the right, 5 is in front, and 6 is behind. `offset` is the fraction of the sprite size to separate it from the point.

When `shapes` is not NULL, it should be a vector of identifiers of objects to plot in the scene (e.g. as returned by plotting functions or by `ids3d`). These objects will be removed from the scene and duplicated as a sprite image in a constant orientation, as specified by `userMatrix`. By default the origin `(0, 0, 0)` will be plotted at the coordinates given by `(x, y, z)`, perhaps modified by `adj` or `pos`.

The `userMatrix` argument is ignored for `shapes = NULL`. For shapes, `sprites3d` defaults the matrix to `r3dDefaults$userMatrix`.

If any coordinate is NA, the sprite is not plotted.

The id values of the shapes may be retrieved after plotting using `rgl.attrib(id, "ids")`; the user matrix is retrieved using `rgl.attrib(id, "usermatrix")`. 
These functions are called for the side effect of displaying the sprites. The shape ID of the displayed object is returned.

open3d()
particles3d( rnorm(100), rnorm(100), rnorm(100), color = rainbow(100) )
# is the same as
sprites3d( rnorm(100), rnorm(100), rnorm(100), color = rainbow(100),
  lit = FALSE, alpha = .2,
  textype = "alpha", texture = system.file("textures/particle.png", package = "rgl")
)  
sprites3d( rnorm(10) + 6, rnorm(10), rnorm(10), shape = shade3d(tetrahedron3d(), col = "red") )

subdivision3d  Subdivide a mesh

Description

The subdivision surface algorithm divides and refines (deforms) a given mesh recursively to certain degree (depth). The mesh3d algorithm consists of two stages: divide and deform. The divide step generates for each triangle or quad four new triangles or quads, the deform step drags the points (refinement step).

Usage

subdivision3d( x, ... )
  ## S3 method for class 'mesh3d'
subdivision3d( x, depth = 1, normalize = FALSE, deform = TRUE, ... )
divide.mesh3d(mesh, vb = mesh$vb, ib = mesh$ib, it = mesh$it )
normalize.mesh3d(mesh)
deform.mesh3d(mesh, vb = mesh$vb, ib = mesh$ib, it = mesh$it )

Arguments

  x  3d geometry mesh
  mesh  3d geometry mesh
  depth  recursion depth
  normalize  normalize mesh3d coordinates after division if deform is TRUE
  deform  deform mesh
  it  indices for triangular faces
  ib  indices for quad faces
vb matrix of vertices: 4 x n matrix (rows x, y, z, h) or equivalent vector, where h indicates scaling of each plotted quad
...
other arguments (unused)

Details

subdivision3d takes a mesh object and replaces each triangle or quad with 4 new ones by adding vertices half-way along the edges (and one in the centre of a quad). The positions of the vertices are deformed so that the resulting surface is smoother than the original. These operations are repeated depth times.

The other functions do the individual steps of the subdivision. divide.mesh3d adds the extra vertices. deform.mesh3d does the smoothing by replacing each vertex with the average of each of its neighbours. normalize.mesh3d normalizes the homogeneous coordinates, by setting the 4th coordinate to 1. (The 4th coordinate is used as a weight in the deform step.)

Examples

open3d()
shade3d( subdivision3d( cube3d(), depth = 3 ), color = "red", alpha = 0.5 )

subscene3d

Create, select or modify a subscene

Description

This creates a new subscene, or selects one by id value, or adds objects to one.

Usage

newSubscene3d(viewport = "replace",
project = "replace",
model = "replace",
mouseMode = "inherit",
parent = currentSubscene3d(),
copyLights = TRUE,
copyShapes = FALSE,
copyBBoxDeco = copyShapes,
copyBackground = FALSE, newviewport,
ignoreExtent)
currentSubscene3d(dev = cur3d())
useSubscene3d(subscene)
addToSubscene3d(ids = tagged3d(tags), tags, subscene = currentSubscene3d())
deleteSubscene3d(ids = tagged3d(tags), tags, subscene = currentSubscene3d())
gc3d(protect = NULL)
Arguments

viewport, projection, model, mouseMode
   How should the new subscene be embedded? Possible values are c("inherit","modify","replace"). See Details below.

parent
   The parent subscene (defaults to the current subscene).

copyLights, copyShapes, copyBBoxDeco, copyBackground
   Whether lights, shapes, bounding box decorations and background should be copied to the new subscene.

newviewport
   Optionally specify the new subscene’s viewport (in pixels).

ignoreExtent
   Whether to ignore the subscene’s bounding box when calculating the parent bounding box. Defaults to TRUE if model is not "inherit".

dev
   Which RGL device to query for the current subscene.

subscene
   Which subscene to use or modify.

ids
   A vector of integer object ids to add to the subscene.

tags
   Alternate way to specify ids. Ignored if ids is given.

protect
   Object ids to protect from this garbage collection.

Details

The rgl package allows multiple windows to be open; each one corresponds to a “scene”. Within each scene there are one or more “subscenes”. Each subscene corresponds to a rectangular region in the window, and may have its own projection, transformation and behaviour in response to the mouse.

There is always a current subscene: most graphic operations make changes there, e.g. by adding an object to it.

The scene “owns” objects; addToSubscene3d and delFromSubscene3d put their ids into or remove them from the list being displayed within a particular subscene. The gc3d function deletes objects from the scene if they are not visible in any subscene, unless they are protected by having their id included in protect.

The viewport, projection and model parameters each have three possible settings: c("inherit","modify","replace"). "inherit" means that the corresponding value from the parent subscene will be used. "replace" means that the new subscene will have its own value of the value, independent of its parent. "modify" means that the child value will be applied first, and then the parent value will be applied. For viewport, this means that if the parent viewport is changed, the child will maintain its relative position. For the two matrices, "modify" is unlikely to give satisfactory results, but it is available for possible use.

The mouseMode parameter can only be one of c("inherit","replace"). If it is "inherit", the subscene will use the mouse controls of the parent, and any change to them will affect the parent and all children that inherit from it. This is the behaviour that was present before rgl version 0.100.13. If it is "replace", then it will receive a copy of the parent mouse controls, but modifications to them will affect only this subscene, not the parent. Note that this is orthogonal to the par3d("listeners") setting: if another subscene is listed as a listener, it will respond to mouse actions using the same mode as the one receiving them.
The viewport parameter controls the rectangular region in which the subscene is displayed. It is specified using newviewport (in pixels relative to the whole window), or set to match the parent viewport.

The projection parameter controls settings corresponding to the observer. These include the field of view and the zoom; they also include the position of the observer relative to the model. The \( \text{par3d}(\text{"projMatrix"}) \) matrix is determined by the projection.

The model parameter controls settings corresponding to the model. Mouse rotations affect the model, as does scaling. The \( \text{par3d}(\text{"modelMatrix"}) \) matrix is determined by these as well as by the position of the observer (since OpenGL assumes that the observer is at \((0, 0, 0)\) after the \text{MODELVIEW} transformation). Only those parts concerning the model are inherited when model specifies inheritance, the observer setting is controlled by projection.

If copyBackground is TRUE, the background of the newly created child will overwrite anything displayed in the parent subscene, regardless of depth.

\section*{Value}

If successful, each function returns the object id of the subscene, with the exception of gc3d, which returns the count of objects which have been deleted, and useSubscene3d, which returns the previously active subscene id.

\section*{Author(s)}

Duncan Murdoch and Fang He.

\section*{Examples}

```r
# Show the Earth with a cutout by using clipplanes in subscenes
lat <- matrix(seq(90, -90, len = 50)*pi/180, 50, 50, byrow = TRUE)
long <- matrix(seq(-180, 180, len = 50)*pi/180, 50, 50)

r <- 6378.1  # radius of Earth in km
x <- r*cos(lat)*cos(long)
y <- r*cos(lat)*sin(long)
z <- r*sin(lat)

open3d()
obj <- surface3d(x, y, z, col = "white",
    texture = system.file("textures/worldsmall.png", package = "rgl"),
    specular = "black", axes = FALSE, box = FALSE, xlab = "", ylab = "", zlab = "",
    normal_x = x, normal_y = y, normal_z = z)

cols <- c(rep("chocolate4", 4), rep("burlywood1", 4), "darkgoldenrod1")
rs <- c(6350, 5639, 4928.5, 4207, 3486,
```

for (i in seq_along(rs))
  obj <- c(obj, spheres3d(0, 0, col = cols[i], radius = rs[i]))

root <- currentSubscene3d()

newSubscene3d("inherit", "inherit", "inherit", copyShapes = TRUE, parent = root)
clipplanes3d(1, 0, 0, 0)

newSubscene3d("inherit", "inherit", "inherit", copyShapes = TRUE, parent = root)
clipplanes3d(0, 1, 0, 0)

newSubscene3d("inherit", "inherit", "inherit", copyShapes = TRUE, parent = root)
clipplanes3d(0, 0, 1, 0)

# Now delete the objects from the root subscene, to reveal the clipping planes
useSubscene3d(root)
delFromSubscene3d(obj)

---

### subsceneInfo

**Get information on subscenes**

#### Description

This function retrieves information about the tree of subscenes shown in the active window.

#### Usage

```r
subsceneInfo(id = NA, embeddings, recursive = FALSE)
```

#### Arguments

- `id` - Which subscene to report on; `NA` is the current subscene. Set to "root" for the root.
- `embeddings` - Optional new setting for the embeddings for this subscene.
- `recursive` - Whether to report on children recursively.

#### Details

In RGL, each window contains a tree of "subscenes", each containing views of a subset of the objects defined in the window.

Rendering in each subscene depends on the viewport, the projection, and the model transformation. Each of these characteristics may be inherited from the parent (embedding[i] = "inherit"), may modify the parent (embedding[i] = "modify"), or may replace the parent (embedding[i] == "replace"). All three must be specified if embeddings is used.
Value

- id: The object id of the subscene.
- parent: The object id of the parent subscene, if any.
- children: If recursive, a list of the information for the children, otherwise just their object ids.
- embedding: A vector of 3 components describing how this subscene is embedded in its parent.

- subsceneInfo()

---

(surface3d)  
*Add surface*

Description

Adds a surface to the current scene. The surface is defined by a matrix defining the height of each grid point and two vectors defining the grid.

Usage

surface3d(x, y, z, ..., normal_x = NULL, normal_y = NULL, normal_z = NULL)
terrain3d(x, y, z, ..., normal_x = NULL, normal_y = NULL, normal_z = NULL)

Arguments

- `x`: values corresponding to rows of `z`, or matrix of x coordinates.
- `y`: values corresponding to the columns of `z`, or matrix of y coordinates.
- `z`: matrix of heights.
- `...`: Material and texture properties. See `rgl.material` for details.
- `normal_x`, `normal_y`, `normal_z`: matrices of the same dimension as `z` giving the coordinates of normals at each grid point.
Details

Adds a surface mesh to the current scene. The surface is defined by the matrix of height values in \( z \), with rows corresponding to the values in \( x \) and columns corresponding to the values in \( y \). This is the same parametrization as used in \texttt{persp}.

If the \( x \) or \( y \) argument is a matrix, then it must be of the same dimension as \( z \), and the values in the matrix will be used for the corresponding coordinates. This is used to plot shapes such as cylinders where \( z \) is not a function of \( x \) and \( y \).

If the normals are not supplied, they will be calculated automatically based on neighbouring points. \texttt{surface3d} always draws the surface with the ‘front’ upwards (i.e. towards higher \( z \) values). This can be used to render the top and bottom differently; see \texttt{rgl.material} and the example below.

For more flexibility in defining the surface, use \texttt{rgl.surface}.

\texttt{surface3d} and \texttt{terrain3d} are synonyms.

See Also

\texttt{rgl.material, rgl.surface}. See \texttt{persp3d} for a higher level interface.

Examples

```r
# volcano example taken from "persp"
#
# z <- 2 * volcano # Exaggerate the relief
x <- 10 * (1:nrow(z)) # 10 meter spacing (S to N)
y <- 10 * (1:ncol(z)) # 10 meter spacing (E to W)
zlim <- range(z)
colorlut <- terrain.colors(zlen) # height color lookup table
col <- colorlut[ z - zlim[1] + 1 ] # assign colors to heights for each point
open3d()
surface3d(x, y, z, color = col, back = "lines")
```

---

tagged3d

Find tags on rgl objects.

Description

Objects with material properties may have an arbitrary string set as a tag. This function retrieves the id values associated with a given tag, or the tags set on given ids.
tagged3d

Usage

tagged3d(tags = NULL, ids = NULL, full = FALSE, subscene = 0)

Arguments

tag A vector of tags to use for selection.
ids A vector of ids to report the tags on.
full logical; whether to return a dataframe containing id, type, tag, or a vector of
ids or tags.
subscene Where to look: by default, the whole scene is searched. NA restricts the search
to the current subscene, or a subscene id can be given.

Details

Exactly one of tags and ids must be specified.

Value

A dataframe is constructed with columns

<table>
<thead>
<tr>
<th>id</th>
<th>item id</th>
</tr>
</thead>
<tbody>
<tr>
<td>type</td>
<td>item type</td>
</tr>
<tr>
<td>tag</td>
<td>item tag</td>
</tr>
</tbody>
</table>

matching the specified tags or ids value. If full = TRUE, the full dataframe is returned, otherwise
just the requested ids or tags.

If ids is specified, the return value will be in the same order as ids).

Author(s)

Duncan Murdoch

Examples

open3d()
ids <- plot3d(rnorm(10), rnorm(10), rnorm(10), tag = "plot")
unclass(ids)
tagged3d("plot")
tagged3d(ids = ids, full = TRUE)
text3d

Add text to plot

Description

Adds text to the scene. The text is positioned in 3D space. Text is always oriented towards the camera.

Usage

text3d(x, y = NULL, z = NULL, texts, adj = 0.5, pos = NULL, offset = 0.5,
usePlotmath = is.language(texts), ...)
texts3d(x, y = NULL, z = NULL, texts, adj = 0.5, pos = NULL, offset = 0.5,
usePlotmath = is.language(texts), ...)

Arguments

x, y, z point coordinates. Any reasonable way of defining the coordinates is acceptable. See the function xyz.coords for details.
texts text character vector to draw
adj one value specifying the horizontal adjustment, or two, specifying horizontal and vertical adjustment respectively, or three, specifying adjustment in all three directions.
pos a position specifier for the text. If specified, this overrides any adj value given. Values of 0, 1, 2, 3, 4, 5, 6 respectively indicate positions at, below, to the left of, above, to the right of, in front of, and behind the specified coordinates.
offset when pos is specified, this value gives the offset of the label from the specified coordinate in fractions of a character width.
usePlotmath logical. Should plotmath3d be used for the text?
...

In the other functions, additional parameters to pass to rgl.texts.

Details

The adj parameter determines the position of the text relative to the specified coordinate. Use adj = c(0, 0) to place the left bottom corner at (x, y, z), adj = c(0.5, 0.5) to center the text there, and adj = c(1,1) to put the right top corner there. The optional second coordinate for vertical adjustment defaults to 0.5. Placement is done using the "advance" of the string and the "ascent" of the font relative to the baseline, when these metrics are known.
text3d and texts3d draw text using the r3d conventions. These are synonyms; the former is singular to be consistent with the classic 2-D graphics functions, and the latter is plural to be consistent with all the other graphics primitives. Take your choice!
If any coordinate or text is NA, that text is not plotted.
If usePlotmath is TRUE, the work will be done by the plotmath3d function instead of rgl.texts. This is the default if the texts parameter is "language", e.g. the result of a call to expression or quote.
thigmophobe3d

Value

The text drawing functions return the object ID of the text object (or sprites, in case of usePlotmath
= TRUE) invisibly.

See Also

r3d, rgl.texts, plotmath3d, rglExtrafonts for adding fonts

Examples

open3d()

famnum <- rep(1:3, 8)
family <- c("serif", "sans", "mono")[famnum]
font <- rep(rep(1:4, each = 3), 2)
cex <- rep(1:2, each = 12)
text3d(font, cex, famnum, text = paste(family, font), adj = 0.5,
      color = "blue", family = family, font = font, cex = cex)

thigmophobe3d

Find the direction away from the closest point in a 3d projection

Description

Jim Lemon’s thigmophobe function in the plotrix package computes good directions for labels in
a 2D plot. This function does the same for a particular projection in a 3D plot by projecting down
to 2D and calling his function.

Usage

thigmophobe3d(x, y = NULL, z = NULL,
             P = par3d("projMatrix"),
             M = par3d("modelMatrix"),
             windowRect = par3d("windowRect"))

Arguments

x, y, z
point coordinates. Any reasonable way of defining the coordinates is acceptable. See the function xyz.coords for details.

P, M, windowRect
The projection and modelview matrices, and the size and position of the display in pixels.

Details

Since thigmophobe3d projects using fixed P and M, it will not necessarily choose good directions if
the user rotates the display or makes any other change to the projection.
Value

A vector of values from 1 to 4 to be used as the pos argument in text3d.

Note

The example below shows how to update the directions during an animation; I find that the moving labels are distracting, and prefer to live with fixed ones.

      # Need to rotate before thigmophobe3d is called
      result <- spin(time)
      par3d(userMatrix = result$userMatrix)
      textid <<- text3d(xyz, texts = 1:10, pos = thigmophobe3d(xyz))
      result
    }
    play3d(f, duration = 5)
  } else
    textid  # just print the static display
}
Description

This function opens a TCL/TK modal dialog to allow particular views of an RGL scene to be saved.

Usage

tkpar3dsave(params = c("userMatrix", "scale", "zoom", "FOV"),
              times = FALSE, dev = cur3d(), ...)

Arguments

params Which parameters to save
times Should times be saved as well?
dev Which RGL device to work with
... Additional parameters to pass to tktoplevel

Details

This opens a TCL/TK modal dialog box with Record and Quit buttons. Each time Record is clicked, a snapshot is taken of current par3d settings. When Quit is clicked, the dialog closes and the values are returned in a list.

If times == TRUE, then the times at which the views are recorded will also be saved, so that the play3d function will play back with the same timing.

Value

A list of the requested components. Each one will consist of a list of values that were current when the Record button was clicked. These are suitable to be passed directly to the par3dinterp function.

Examples

```r
if (interactive() && !in_pkgdown_example()) {

  # Record a series of positions, and then play them back immediately
  # at evenly spaced times, in an oscillating loop
  example(plot3d)
  play3d(par3dinterp(tkpar3dsave()) )

  # As above, but preserve the click timings
  # play3d(par3dinterp(tkpar3dsave(times=TRUE) ) )
}
```

---

tkrgl

The former tkrgl package

Description

Functions from the former tkrgl package.

Details

The tkrgl package contained functions to use TCL/TK to control an RGL scene on screen. These functions have now been merged into the rgl package, and the tkrgl package has been archived.

To avoid conflicts with RGL names and to indicate the TCL/TK nature of these functions, they have all been prefixed with `tk`:

- **tkpar3dsave** Formerly tkrgl::par3dsave, allows interactive saving of scene parameters.
- **tkspin3d, tkspinControl** Formerly tkrgl::spin3d and tkrgl::spinControl, create buttons to spin the scene.

History:

- 0.2-2 First public release
- 0.3 Added possibility to control multiple windows
- 0.4 Compatibility with 2.0.0 tcltk package
- 0.5 Added continuous rotation
- 0.6 Added par3dsave
- 0.7 Added parameters to tkspinControl, fixed startup
- 0.8 Minor fixes to pass checks
- 0.9 Merge functions into rgl

---

tkspin3d

Create TCL/TK controller for RGL window
tkspinControl

Description

This function creates a TCL/TK window containing buttons to spin and resize one or more RGL windows.

Usage

\begin{verbatim}
tkspin3d(dev = cur3d(), ...)
\end{verbatim}

Arguments

\begin{itemize}
\item \texttt{dev} A vector of one or more RGL device numbers to control
\item \texttt{...} Named parameters in that match named formal arguments to \texttt{tkspinControl} are passed there, while others are passed to \texttt{tktoplevel}
\end{itemize}

Author(s)

Ming Chen and Duncan Murdoch

\texttt{tkspinControl}

Examples

\begin{verbatim}
if (interactive() && !in_pkgdown_example()) {
  open3d()
  points3d(rnorm(100), rnorm(100), rnorm(100), size=3)
  axes3d()
  box3d()
  tkspin3d()
}
\end{verbatim}

\begin{itemize}
\item \texttt{tkspinControl} Create a spin control in a TCL/TK window
\end{itemize}

Description

This function may be used to embed a spin control in a TCL/TK window.

Usage

\begin{verbatim}
tkspinControl(base, dev = cur3d(),
  continue=FALSE, speed=30, scale=100, ...)
\end{verbatim}
Arguments

base The TCL/TK frame in which to insert this control.
dev A vector of one or more RGL device numbers to control.
continue Initial setting for continuous rotation checkbox.
speed Initial setting for speed slider.
scale Initial setting for scale slider.
... Additional parameters to pass to tkframe

  tkpack(con1, con2)
}
toggleWidget

An HTML widget to toggle display of elements of a scene

Description

This function produces a button in an HTML scene that will toggle the display of items in the scene.

Usage

toggleWidget(sceneId,
    ids = tagged3d(tags), tags = NULL, hidden = integer(),
    subscenes = NULL,
    label,
    ...
)

Arguments

sceneId The HTML id of the RGL scene being controlled, or an object as in playwidget.
ids, hidden The RGL id numbers of the objects to toggle. Those in ids are initially shown; those in hidden are initially hidden.
tags Alternate way to specify ids. Ignored if ids is given.
subscenes The subscenes in which to toggle the objects.
label The label to put on the button. The default is set from the expression passed to ids or the value of tags.
... Additional arguments to pass to playwidget.

Details

Like playwidget, this function is designed to work within the htmlwidgets framework. If the value is printed, the button will be inserted into the output.

It is also designed to work with magrittr-style pipes: the result of rglwidget or other widgets can be piped into it to add it to a display. It can also appear first in the pipeline, if sceneId is set to NA.

Value

A widget suitable for use in an Rmarkdown-generated web page, or elsewhere.

toggleButton for the older style of HTML control.
Examples

```r
theplot <- plot3d(rnorm(100), rnorm(100), rnorm(100), col = "red")
widget <- rglwidget(height = 300, width = 300) %>%
toggleWidget(theplot["data"],
              hidden = theplot[c("xlab", "ylab", "zlab")],
              label = "Points")
if (interactive() || in_pkgdown_example())
  widget
```

triangulate **Triangulate a two-dimensional polygon**

Description

This algorithm decomposes a general polygon into simple polygons and uses the “ear-clipping” algorithm to triangulate it. Polygons with holes are supported.

Usage

```r
triangulate(x, y = NULL, z = NULL, random = TRUE, plot = FALSE, partial = NA)
```

Arguments

- **x, y, z** Coordinates of a two-dimensional polygon in a format supported by `xyz.coords`. See Details for how z is handled.
- **random** Whether to use a random or deterministic triangulation.
- **plot** Whether to plot the triangulation; mainly for debugging purposes.
- **partial** If the triangulation fails, should partial results be returned?

Details

Normally `triangulate` looks only at the x and y coordinates. However, if one of those is constant, it is replaced with the z coordinate if present.

The algorithm works as follows. First, it breaks the polygon into pieces separated by NA values in x or y. Each of these pieces should be a simple, non-self-intersecting polygon, separate from the other pieces. (Though some minor exceptions to this rule may work, none are guaranteed). The nesting of these pieces is determined.

The “outer” polygon(s) are then merged with the polygons that they immediately contain, and each of these pieces is triangulated using the ear-clipping algorithm.

Finally, all the triangulated pieces are put together into one result.

Value

A three-by-n array giving the indices of the vertices of each triangle. (No vertices are added; only the original vertices are used in the triangulation.)

The array has an integer vector attribute "nextvert" with one entry per vertex, giving the index of the next vertex to proceed counter-clockwise around outer polygon boundaries, clockwise around inner boundaries.
Note

Not all inputs will succeed, even when a triangulation is possible. Generally using random = TRUE will find a successful triangulation if one exists, but it may occasionally take more than one try.

Author(s)

Duncan Murdoch

References

See the Wikipedia article “polygon triangulation” for a description of the ear-clipping algorithm.

extrude3d for a solid extrusion of a polygon, polygon3d for a flat display; both use triangulate.

Examples

theta <- seq(0, 2*pi, len = 25)[-25]
theta <- c(theta, NA, theta, NA, theta, NA, theta, NA, theta)
r <- c(rep(1.5, 24), NA, rep(0.5, 24), NA, rep(0.5, 24), NA, rep(0.3, 24), NA, rep(0.1, 24))
dx <- c(rep(0, 24), NA, rep(0.6, 24), NA, rep(-0.6, 24), NA, rep(-0.6, 24), NA, rep(-0.6, 24))
x <- r*cos(theta) + dx
y <- r*sin(theta)
plot(x, y, type = "n")
polygon(x, y)
triangulate(x, y, plot = TRUE)
open3d()
polygon3d(x, y, x - y, col = "red")

turn3d

Create a solid of rotation from a two-dimensional curve

Description

This function “turns” the curve (as on a lathe) to form a solid of rotation along the x axis.

Usage

turn3d(x, y = NULL, n = 12, smooth = FALSE, ...)

Arguments

x, y Points on the curve, in a form suitable for xy.coords. The y values must be non-negative.
n How many steps in the rotation?
smooth logical; whether to add normals for a smooth appearance.
... Additional parameters to pass to tmesh3d.
Value
A mesh object containing triangles and/or quadrilaterals.

Author(s)
Fang He and Duncan Murdoch

See Also
extrude3d

Examples
\begin{verbatim}
x <- 1:10
y <- rnorm(10)^2
open3d()
shade3d(turn3d(x, y), col = "green")
\end{verbatim}

Description
This is a function to produce actions in a web display. A playwidget or Shiny input control (e.g. a sliderInput control) sets a value which controls attributes of a selection of vertices.

Usage
\begin{verbatim}
vertexControl(value = 0, values = NULL, vertices = 1, attributes, 
objid = tagged3d(tag), tag,
param = seq_len(NROW(values)) - 1, interp = TRUE)
\end{verbatim}

Arguments
\begin{description}
\item[value] The value to use for input (typically input$value in a Shiny app.) Not needed with playwidget.
\item[values] A matrix of values, each row corresponding to an input value.
\item[vertices] Which vertices are being controlled? Specify vertices as a number from 1 to the number of vertices in the objid.
\item[attributes] A vector of attributes of a vertex, from c("x", "y", "z", "red", "green", "blue", "alpha", "nx", "ny", "nz", "radii", "ox", "oy", "oz", "ts", "tt", "offset")
\item[objid] A single RGL object id.
\item[tag] An alternate way to specify objid.
\item[param] Parameter values corresponding to each row of values.
\item[interp] Whether to interpolate between rows of values.
\end{description}
Details

This function modifies attributes of vertices in a single object. The attributes are properties of each vertex in a scene; not all are applicable to all objects. In order, they are: coordinates of the vertex "x", "y", "z", color of the vertex "red", "green", "blue", "alpha", normal at the vertex "nx", "ny", "nz", radius of a sphere at the vertex "radius", origin within a texture "ox", "oy" and perhaps "oz", texture coordinates "ts", "tt".

Planes are handled specially. The coefficients a, b, c in the planes3d or clipplanes3d specification are controlled using "nx", "ny", "nz", and d is handled as "offset". The vertices argument is interpreted as the indices of the planes when these attributes are set.

If only one attribute of one vertex is specified, values may be given as a vector and will be treated as a one-column matrix. Otherwise values must be given as a matrix with ncol(values) == max(length(vertices), length(attributes)). The vertices and attributes vectors will be recycled to the same length, and entries from column j of values will be applied to vertex vertices[j], attribute attributes[j].

The value argument is translated into a row (or two rows if interp = TRUE) of values by finding its location in param.

Value

A list of class "rglControl" of cleaned up parameter values, to be used in an RGL widget.

Author(s)

Duncan Murdoch

Examples

saveopts <- options(rgl.useNULL = TRUE)

theta <- seq(0, 6*pi, len=100)
xyz <- cbind(sin(theta), cos(theta), theta)
plot3d(xyz, type="l")
id <- spheres3d(xyz[1,,drop=FALSE], col="red")

widget <- rglwidget(width=500, height=300) %>%
  playwidget(vertexControl(values=xyz, attributes=c("x", "y", "z"),
                 objid = id, param=1:100),
                start = 1, stop = 100, rate=10)
if (interactive() || in_pkgdown_example())
  widget
options(saveopts)
**viewpoint**  

Set up viewpoint

---

**Description**

Set the viewpoint orientation.

**Usage**

```r
view3d( theta = 0, phi = 15, ...)
rgl.viewpoint( theta = 0, phi = 15, fov = 60, zoom = 1,
               scale = par3d("scale"), interactive = TRUE, userMatrix,
               type = c("userviewpoint", "modelviewpoint") )
```

**Arguments**

- `theta`, `phi`  
  polar coordinates
- `...`  
  additional parameters to pass to `rgl.viewpoint`
- `fov`  
  field-of-view angle in degrees
- `zoom`  
  zoom factor
- `scale`  
  real length 3 vector specifying the rescaling to apply to each axis
- `interactive`  
  logical, specifying if interactive navigation is allowed
- `userMatrix`  
  4x4 matrix specifying user point of view
- `type`  
  which viewpoint to set?

**Details**

The data model can be rotated using the polar coordinates `theta` and `phi`. Alternatively, it can be set in a completely general way using the 4x4 matrix `userMatrix`. If `userMatrix` is specified, `theta` and `phi` are ignored.

The pointing device of your graphics user-interface can also be used to set the viewpoint interactively. With the pointing device the buttons are by default set as follows:

- **left**  
  adjust viewpoint position
- **middle**  
  adjust field of view angle
- **right or wheel**  
  adjust zoom factor

The user’s view can be set with `fov` and `zoom`.

If the `fov` angle is set to 0, a parallel or orthogonal projection is used. Small non-zero values (e.g. 0.01 or less, but not 0.0) are likely to lead to rendering errors due to OpenGL limitations.

Prior to version 0.94, all of these characteristics were stored in one viewpoint object. With that release the characteristics are split into those that affect the projection (the user viewpoint) and those that affect the model (the model viewpoint). By default, this function sets both, but the `type` argument can be used to limit the effect.

par3d

Examples

```r
## Not run:
# animated round trip tour for 10 seconds

rgl.open()
shade3d(oh3d(), color = "red")

start <- proc.time()[3]
while ((i <- 36*(proc.time()[3] - start)) < 360) {
  rgl.viewpoint(i, i/4);
}

## End(Not run)
```

webGLcontrols  

**Obsolete functions to write HTML/Javascript code to control a WebGL display**

Description

These functions write out HTML code to control WebGL displays on the same page. They are deprecated; most documentation has now been removed.

Usage

```r
subsetSlider(subsets, labels = names(subsets),
  fullset = Reduce(union, subsets),
  subscenes = currentSubscene3d(), prefixes = "",
  accumulate = FALSE, ...)

subsetSetter(subsets, fullset = Reduce(union, subsets),
  subscenes = currentSubscene3d(), prefixes = "",
  accumulate = FALSE)

clipplaneSlider(a=NULL, b=NULL, c=NULL, d=NULL,
  plane = 1, clipplaneids, prefixes = "",
  labels = signif(values[1],3), ...)

toggleButton(subset, subscenes = currentSubscene3d(), prefixes = "",
  label = deparse(substitute(subset)),
  id = paste0(basename(tempfile("input"))), name = id)
```
writeASY

Arguments

subsets  A list of vectors of object identifiers; the slider or setter will choose among them.
labels  Labels to display corresponding to each subset. If NULL, numeric labels will be shown.
fullset  Objects in the subscene which are not in fullset will not be touched.
subscenes  The subscenes to be controlled.
prefixes  The prefixes of the WebGL scenes to be controlled.
accumulate  If TRUE, the subsets will accumulate (by union) as the value increases.
id  The id of the input control that will be generated.
name  The name of the input control that will be generated.
...  Arguments to pass to propertySlider.
a,b,c,d  The parameter values to change. Leave as NULL to hold the parameter constant.
plane, clipplaneids  The identifier of the particular clipplane to modify.
subset  The subset that the button should toggle.
label  The button label.

Value

subsetSetter returns a length-one character vector of class "propertySetter".

The other functions use cat to write their output and invisibly return the id of the control that was generated.

playwidget and toggleWidget for a newer, preferred method of inserting controls into a scene.

writeASY  Write Asymptote code for an RGL scene

Description

Asymptote is a language for 3D graphics that is highly integrated with LaTeX. This is an experimental function to write an Asymptote program to approximate an RGL scene.
Usage

writeASY(scene = scene3d(),
          title = "scene",
          outtype = c("pdf", "eps", "asy", "latex", "pdflatex"),
          prc = TRUE,
          runAsy = "asy %filename%",
          defaultFontsize = 12,
          width = 7, height = 7,
          ppi = 100,
          ids = tagged3d(tags),
          tags = NULL,
          version = "2.65")

Arguments

scene RGL scene object
outtype What type of file to write? See Details.
prc Whether to produce an interactive PRC scene.
title The base of the filename to produce.
runAsy Code to run the Asymptote program.
defaultFontsize The default fontsize for text.
width, height Width and height of the output image, in inches.
ppi "Pixels per inch" to assume when converting line widths and point sizes (which
       RGL measures in pixels).
ids If not NULL, write out just these RGL objects.
tags Alternate way to specify ids. Ignored if ids is given.
version Asymptote version 2.44 had a definition for its “light()” function that was in-
       compatibly changed in versions 2.47 and 2.50. The current code has been tested
       with version 2.65. If you are using an older version, set version to your version
       number and it may work better.

Details

Asymptote is both a language describing a 2D or 3D graphic, and a program to interpret that lan-
guage and produce output in a variety of formats including EPS, PDF (interactive or static), etc.
The interactive scene produced with prc = TRUE requires outtype = "pdf", and (as of this writing)
has a number of limitations:

- As far as we know, only Adobe Acrobat Reader of a sufficiently recent version can display
  these scenes.
- Current versions ignore lighting settings.

Value

The filename of the output file is returned invisibly.
Note

This function is currently under development and limited in the quality of output it produces. Arguments will likely change.

There are a number of differences between the interactive display in Asymptote and the display in RGL. In particular, many objects that are a fixed size in RGL will scale with the image in Asymptote. Defaults have been chosen somewhat arbitrarily; tweaking will likely be needed.

Material properties of surfaces are not yet implemented.

On some systems, the program `asy` used to process the output has bugs and may fail. Run the example at your own risk!

Author(s)

Duncan Murdoch

References

See Also

`scene3d` saves a copy of a scene to an R variable; `rglwidget, writePLY, writeOBJ` and `writeSTL` write the scene to a file in various other formats.

Examples

```r
## Not run:
# On some systems, the program "asy" used
# to process the output has bugs, so this may fail.
x <- rnorm(20)
y <- rnorm(20)
z <- rnorm(20)
plot3d(x, y, z, type = "s", col = "red")
olddir <- setwd(tempdir())
writeASY(title = "interactive") # Produces interactive.pdf
writeASY(title = "noninteractive", prc = FALSE) # Produces noninteractive.pdf
setwd(olddir)

## End(Not run)
```

writeOBJ

Read and write Wavefront OBJ format files

Description

writeOBJ writes OBJ files. This is a file format that is commonly used in 3D graphics applications. It does not represent text, but does represent points, lines, polygons (and many other types that RGL doesn’t support). readOBJ reads only some parts of OBJ files.
writeOBJ

Usage

writeOBJ(con, 
pointRadius = 0.005, pointShape = icosahedron3d(), 
lineRadius = pointRadius, lineSides = 20, 
pointsAsPoints = FALSE, linesAsLines = FALSE, 
withNormals = TRUE, withTextures = TRUE, 
separateObjects = TRUE, 
ids = tagged3d(tags), 
tags = NULL)
readOBJ(con, ...)

Arguments

con A connection or filename.
pointRadius, lineRadius The radius of points and lines relative to the overall scale of the figure, if they are converted to polyhedra.
pointShape A mesh shape to use for points if they are converted. It is scaled by the pointRadius.
lineSides Lines are rendered as cylinders with this many sides.
pointsAsPoints, linesAsLines Whether to convert points and lines to “point” and “line” records in the OBJ output.
withNormals Whether to output vertex normals for smooth shading.
separateObjects Whether to mark each RGL object as a separate object in the file.
withTextures Whether to output texture coordinates.
ids The identifiers (from ids3d) of the objects to write. If NULL, try to write everything.
tags Alternate way to specify ids. Ignored if ids is given.
... Additional arguments (typically just material) to pass to tmesh3d.

Details

The current writeOBJ implementation only outputs triangles, quads, planes, spheres, points, line segments, line strips and surfaces. It does not output material properties such as colors, since the OBJ format does not support the per-vertex colors that RGL uses.

The readOBJ implementation can read faces, normals, and textures coordinates, but ignores material properties (including the specification of the texture file to use). To read a file that uses a single texture, specify it in the material argument, e.g. readOBJ("model.OBJ", material = list(color = "white", texture = "texture.png")). There is no support for files that use multiple textures.

The defaults for pointsAsPoints and linesAsLines have been chosen because Blender (https://www.blender.org) does not import points or lines, only polygons. If you are exporting to other software you may want to change them.

If present, texture coordinates are output by default, but the textures themselves are not.
Individual RGL objects are output as separate objects in the file when `separateObjects = TRUE`, the default. The output file should be readable by Blender and Meshlab; the latter can write in a number of other formats, including U3D, suitable for import into a PDF document.

Value
writeObj invisibly returns the name of the connection to which the data was written.
readObj returns a mesh object constructed from the input file.

Author(s)
Duncan Murdoch

References
The file format was found at [http://www.martinreddy.net/gfx/3d/OBJ.spec](http://www.martinreddy.net/gfx/3d/OBJ.spec) on November 11, 2012.

See Also
scene3d saves a copy of a scene to an R variable; rglwidget.writeASY, writePLY and writeSTL write the scene to a file in various other formats.

Examples
```r
filename <- tempfile(fileext = ".obj")
open3d()
shade3d( icosahedron3d() )
writeOBJ(filename)

# The motivation for writing readObj() was to read a shape
# file of Comet 67P/Churyumov-Gerasimenko, from the ESA.
# The file no longer appears to be online, but may still be
# available on archive.org. Here was the original URL:
# cometurl <- "http://sci.esa.int/science-e/www/object/doc.cfm?fobjectid=54726"
# This code would read and display it:
# open3d()
# shade3d(readOBJ(url(cometurl),
# material = list(col = "gray")))

# Textures are used in a realistic hand image available from
# https://free3d.com/3d-model/freerealsichand-85561.html
# Thanks to Monte Shaffer for pointing this out.
# Decompress the files into the current directory, convert
# hand_mapNew.jpg to hand_mapNew.png, then use
## Not run:
open3d()
shade3d(readOBJ("hand.OBJ", material = list(color = "white",
shininess = 1, texture = "hand_mapNew.png")))
```
writePLY

Write Stanford PLY format files

Description

This function writes PLY files. This is a simple file format that is commonly used in 3D printing. It does not represent text, only edges and polygons. The writePLY function does the necessary conversions.

Usage

```r
writePLY(con, format = c("little_endian", "big_endian", "ascii"),
  pointRadius = 0.005, pointShape = icosahedron3d(),
  lineRadius = pointRadius, lineSides = 20,
  pointsAsEdges = FALSE, linesAsEdges = pointsAsEdges,
  withColors = TRUE, withNormals = !(pointsAsEdges || linesAsEdges),
  ids = tagged3d(tags), tags = NULL)
```

Arguments

- **con**: A connection or filename.
- **format**: Which output format. Defaults to little-endian binary.
- **pointRadius, lineRadius**: The radius of points and lines relative to the overall scale of the figure, if they are converted to polyhedra.
- **pointShape**: A mesh shape to use for points if they are converted. It is scaled by the pointRadius.
- **lineSides**: Lines are rendered as cylinders with this many sides.
- **pointsAsEdges, linesAsEdges**: Whether to convert points and lines to “Edge” records in the PLY output.
- **withColors**: Whether to output vertex color information.
- **withNormals**: Whether to output vertex normals for smooth shading.
- **ids**: The identifiers (from `ids3d`) of the objects to write. If NULL, try to write everything.
- **tags**: Select objects with matching tags. Ignored if `ids` is specified.

Details

The current implementation only outputs triangles, quads, planes, spheres, points, line segments, line strips and surfaces.

The defaults for `pointsAsEdges` and `linesAsEdges` have been chosen because Blender (https://www.blender.org) does not import lines, only polygons. If you are exporting to other software you may want to change them.
writeWebGL

Since the PLY format only allows one object per file, all RGL objects are combined into a single object when output.

The output file is readable by Blender and Meshlab; the latter can write in a number of other formats, including U3D, suitable for import into a PDF document.

Value

Invisibly returns the name of the connection to which the data was written.

Duncan Murdoch

References

The file format was found on https://www.mathworks.com on November 10, 2012 at a URL that no longer exists; currently the format is described at https://www.mathworks.com/help/vision/ug/the-ply-format.html.

See Also

scene3d saves a copy of a scene to an R variable; rglwidget, writeASY, writeOBJ and writeSTL write the scene to a file in various other formats.

Examples

```r
filename <- tempfile(fileext = ".ply")
open3d()
shade3d( icosahedron3d(col = "magenta") )
writePLY(filename)
```

```r
writeWebGL(dir = "webGL", filename = file.path(dir, "index.html"),
            template = system.file(file.path("WebGL", "template.html"), package = "rgl"),
            prefix = "",
            snapshot = TRUE, commonParts = TRUE, reuse = NULL,
            font = "Arial", width, height)
```
writeWebGL

Arguments

- **dir**  Where to write the files.
- **filename**  The filename to use for the main file.
- **template**  The template web page to which to write the Javascript for the scene. See Details below.
- **prefix**  An optional prefix to use on global identifiers in the scene; use different prefixes for different scenes displayed on the same web page. If not blank, it should be a legal identifier in Javascript and HTML.
- **snapshot**  Whether to include a snapshot of the scene, to be displayed in browsers that don’t support WebGL, or a specification of the snapshot to use. See details below.
- **commonParts**  Whether to include parts that would be common to several figures on the same page. Currently this includes a reference to and copy of the ‘CanvasMatrix.js’ file in the output.
- **reuse**  Ignored.
- **font**  The font to use for text.
- **width, height**  The (optional) width and height in pixels of the image to display. If omitted, the par3d("windowRect") dimensions will be used.

Details

This obsolete function writes out a web page containing Javascript that reconstructs the scene in WebGL. It will be formally deprecated in an upcoming release; you should use rglwidget instead in any new code, and start migrating old code there.

The remaining documentation has been removed to discourage use of this function.

Value

The filename is returned.

Note

If commonParts is TRUE, the output includes a binary copy of the CanvasMatrix Javascript library. Its source (including the copyright notice and license for free use) is included in the file named by system.file("htmlwidgets/lib/CanvasMatrix.src.js",package = "rgl").

Author(s)

Duncan Murdoch.

See Also

rglwidget should be used instead of writeWebGL. Other functions which are related: scene3d saves a copy of a scene to an R variable; writeASY, writePLY, writeOBJ and writeSTL write the scene to a file in various other formats.
