Package ‘spatsoc’

March 28, 2020

Title Group Animal Relocation Data by Spatial and Temporal Relationship

Version 0.1.13

Description Detects spatial and temporal groups in GPS relocations. It can be used to convert GPS relocations to gambit-of-the-group format to build proximity-based social networks. In addition, the randomizations function provides data-stream randomization methods suitable for GPS data.

---

**Description**

`build_lines` creates a `SpatialLines` object from a `data.table`. The function accepts a `data.table` with relocation data, individual identifiers a sorting column and a `projection`. The relocation data is transformed into `SpatialLines` for each individual and optionally, each `splitBy`. Relocation data should be in two columns representing the X and Y coordinates.

**Usage**

```r
build_lines(
  DT = NULL,
  projection = NULL,
  id = NULL,
  coords = NULL,
  sortBy = NULL,
  splitBy = NULL
)
```

**Arguments**

- `DT` input `data.table`
- `projection` PROJ.4 character string
- `id` Character string of ID column name
- `coords` Character vector of X coordinate and Y coordinate column names
- `sortBy` Character string of date time column(s) to sort rows by. Must be a POSIXct.
- `splitBy` (optional) character string or vector of grouping column name(s) upon which the grouping will be calculated
Details

The DT must be a `data.table`. If your data is a `data.frame`, you can convert it by reference using `data.table::setDT`.

The `id`, `coords`, `sortBy` (and optional `splitBy`) arguments expect the names of respective columns in DT which correspond to the individual identifier, X and Y coordinates, sorting column, and additional splitting columns.

The projection expects a PROJ.4 character string (such as those available on [https://spatialreference.org/](https://spatialreference.org/)).

The `sortBy` is used to order the input `data.table` when creating `SpatialLines`. It must a `POSIXct` to ensure the rows are sorted by date time.

The `splitBy` argument offers further control building `SpatialLines`. If in your DT, you have multiple temporal groups (e.g.: years) for example, you can provide the name of the column which identifies them and build `SpatialLines` for each individual in each year.

`build_lines` is used by `group_lines` for grouping overlapping lines created from relocations.

Value

`build_lines` returns a `SpatialLines` object with a line for each individual (and optionally `splitBy` combination).

An error is returned when an individual has less than 2 relocations, making it impossible to build a line.

See Also

`group_lines`

Other Build functions: `build_polys()`

Examples

```r
# Load data.table
library(data.table)

# Read example data
DT <- fread(system.file("extdata", "DT.csv", package = "spatsoc"))

# Cast the character column to POSIXct
DT[, datetime := as.POSIXct(datetime, tz = "UTC")]

# Proj4 string for example data
utm <- '+proj=utm +zone=36 +south +ellps=WGS84 +datum=WGS84 +units=m +no_defs'

# Build lines for each individual
build_lines(DT, projection = utm, id = 'ID', coords = c('X', 'Y'),
            sortBy = 'datetime')

# Build lines for each individual by year
DT[, yr := year(datetime)]
build_lines(DT, projection = utm, id = 'ID', coords = c('X', 'Y'),
```
### Description

`build_polys` creates a `SpatialPolygons` object from a `data.table`. The function accepts a `data.table` with relocation data, individual identifiers, a projection, `hrType` and `hrParams`. The relocation data is transformed into `SpatialPolygons` for each individual and optionally, each `splitBy`. Relocation data should be in two columns representing the X and Y coordinates.

### Usage

```r
build_polys(
    DT = NULL,
    projection = NULL,
    hrType = NULL,
    hrParams = NULL,
    id = NULL,
    coords = NULL,
    splitBy = NULL,
    spPts = NULL
)
```

### Arguments

- **DT**: input `data.table`
- **projection**: PROJ.4 character string
- **hrType**: type of HR estimation, either 'mcp' or 'kernel'
- **hrParams**: a named list of parameters for `adehabitatHR` functions
- **id**: Character string of ID column name
- **coords**: Character vector of X coordinate and Y coordinate column names
- **splitBy**: (optional) character string or vector of grouping column name(s) upon which the grouping will be calculated
- **spPts**: alternatively, provide solely a `SpatialPointsDataFrame` with one column representing the ID of each point.

### Details

The `DT` must be a `data.table`. If your data is a `data.frame`, you can convert it by reference using `data.table::setDT`.

The `id`, `coords` (and optional `splitBy`) arguments expect the names of respective columns in `DT` which correspond to the individual identifier, X and Y coordinates, and additional grouping columns.
The projection expects a PROJ.4 character string (such as those available on https://spatialreference.org/). `build_polys` expects planar coordinates (not unprojected latitude, longitude).

The `hrType` must be either one of "kernel" or "mcp". The `hrParams` must be a named list of arguments matching those of `adehabitatHR::kernelUD` and `adehabitatHR::getverticeshr` or `adehabitatHR::mcp`.

The `splitBy` argument offers further control building `SpatialPolygons`. If in your `DT`, you have multiple temporal groups (e.g.: years) for example, you can provide the name of the column which identifies them and build `SpatialPolygons` for each individual in each year.

group_polys uses `build_polys` for grouping overlapping polygons created from relocations.

Value

`build_polys` returns a `SpatialPolygons` object with a polyon for each individual (and optionally `splitBy` combination).

An error is returned when `hrParams` do not match the arguments of the `hrType adehabitatHR` function.

`group_polys`

Other Build functions: `build_lines()`

Examples

```r
# Load data.table
library(data.table)

# Read example data
DT <- fread(system.file("extdata", "DT.csv", package = "spatsoc"))

# Cast the character column to POSIXct
DT[, datetime := as.POSIXct(datetime, tz = "UTC")]

# Proj4 string for example data
utm <- '+proj=utm +zone=36 +south +ellps=WGS84 +datum=WGS84 +units=m +no_defs'

# Build polygons for each individual using kernelUD and getverticeshr
build_polys(DT, projection = utm, hrType = 'kernel',
            hrParams = list(grid = 60, percent = 95),
            id = 'ID', coords = c('X', 'Y'))

# Build polygons for each individual by year
DT[, yr := year(datetime)]
build_polys(DT, projection = utm, hrType = 'mcp', hrParams = list(percent = 95),
            id = 'ID', coords = c('X', 'Y'), splitBy = 'yr')

# Build polygons from SpatialPointsDataFrame
library(sp)
pts <- SpatialPointsDataFrame(coords = DT[, .(X, Y)],
                               proj4string = CRS(utm),
                               ...)
```

data = DT[, .(ID)]

build_polys(spPts = pts, hrType = 'mcp', hrParams = list(percent = 95))

---

**DT**

*Movement of 10 "Newfoundland Bog Cows"*

---

**Description**

A dataset containing the GPS relocations of 10 individuals in winter 2016-2017.

**Format**

A data.table with 14297 rows and 5 variables:

- **ID** individual identifier
- **X** X coordinate of the relocation (UTM 21N)
- **Y** Y coordinate of the relocation (UTM 21N)
- **datetime** character string representing the date time
- **population** sub population within the individuals

**Examples**

```r
# Load data.table
library(data.table)

# Read example data
DT <- fread(system.file("extdata", "DT.csv", package = "spatsoc"))
```

---

**dyad_id**

*Dyad ID*

---

**Description**

Generate a dyad ID for edge list generated by `edge_nn` or `edge_dist`.

**Usage**

```r
dyad_id(DT = NULL, id1 = NULL, id2 = NULL)
```

**Arguments**

- **DT** input data.table with columns id1 and id2, as generated by `edge_dist` or `edge_nn`
- **id1** ID1 column name generated by `edge_dist` or `edge_nn`
- **id2** ID2 column name generated by `edge_dist` or `edge_nn`
**Details**

An undirected edge identifier between, for example individuals A and B will be A-B (and reverse B and A will be A-B). Internally sorts and pastes id columns. More details in the edge and dyad vignette (in progress).

**Value**

dyad_id returns the input data.table with appended "dyadID" column

**Examples**

```r
# Load data.table
library(data.table)

# Read example data
DT <- fread(system.file("extdata", "DT.csv", package = "spatsoc"))

# Cast the character column to POSIXct
DT[, datetime := as.POSIXct(datetime, tz = "UTC")]

# Temporal grouping
group_times(DT, datetime = 'datetime', threshold = '20 minutes')

# Edge list generation
edges <- edge_dist(
  DT,
  threshold = 100,
  id = 'ID',
  coords = c('X', 'Y'),
  timegroup = 'timegroup',
  returnDist = TRUE,
  fillNA = TRUE
)

# Generate dyad IDs
dyad_id(edges, 'ID1', 'ID2')
```

---

**edge_dist**

**Distance based edge lists**

**Description**

`edge_dist` returns edge lists defined by a spatial distance within the user defined threshold. The function accepts a data.table with relocation data, individual identifiers and a threshold argument. The threshold argument is used to specify the criteria for distance between points which defines a group. Relocation data should be in two columns representing the X and Y coordinates.
Usage

edge_dist(
  DT = NULL,
  threshold = NULL,
  id = NULL,
  coords = NULL,
  timegroup = NULL,
  splitBy = NULL,
  returnDist = FALSE,
  fillNA = TRUE
)

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DT</td>
<td>input data.table</td>
</tr>
<tr>
<td>threshold</td>
<td>distance for grouping points, in the units of the coordinates</td>
</tr>
<tr>
<td>id</td>
<td>Character string of ID column name</td>
</tr>
<tr>
<td>coords</td>
<td>Character vector of X coordinate and Y coordinate column names</td>
</tr>
<tr>
<td>timegroup</td>
<td>timegroup field in the DT upon which the grouping will be calculated</td>
</tr>
<tr>
<td>splitBy</td>
<td>(optional) character string or vector of grouping column name(s) upon which the grouping will be calculated</td>
</tr>
<tr>
<td>returnDist</td>
<td>boolean indicating if the distance between individuals should be returned. If FALSE (default), only ID1, ID2 columns (and timegroup, splitBy columns if provided) are returned. If TRUE, another column &quot;distance&quot; is returned indicating the distance between ID1 and ID2.</td>
</tr>
<tr>
<td>fillNA</td>
<td>boolean indicating if NAs should be returned for individuals that were not within the threshold distance of any other. If TRUE, NAs are returned. If FALSE, only edges between individuals within the threshold distance are returned.</td>
</tr>
</tbody>
</table>

Details

The DT must be a data.table. If your data is a data.frame, you can convert it by reference using data.table::setDT.

The id, coords (and optional timegroup and splitBy) arguments expect the names of a column in DT which correspond to the individual identifier, X and Y coordinates, timegroup (generated by group_times) and additional grouping columns.

The threshold must be provided in the units of the coordinates. The threshold must be larger than 0. The coordinates must be planar coordinates (e.g.: UTM). In the case of UTM, a threshold = 50 would indicate a 50m distance threshold.

The timegroup argument is optional, but recommended to pair with group_times. The intended framework is to group rows temporally with group_times then spatially with edge_dist (or grouping functions).

The splitBy argument offers further control over grouping. If within your DT, you have multiple populations, subgroups or other distinct parts, you can provide the name of the column which identifies them to splitBy. edge_dist will only consider rows within each splitBy subgroup.
Value

dataDist returns a data.table with columns ID1, ID2, timegroup (if supplied) and any columns provided in splitBy. If 'returnDist' is TRUE, column 'distance' is returned indicating the distance between ID1 and ID2.

The ID1 and ID2 columns represent the edges defined by the spatial (and temporal with group_times) thresholds.

See Also

Other Edge-list generation: edge_nn()

Examples

# Load data.table
library(data.table)

# Read example data
DT <- fread(system.file("extdata", "DT.csv", package = "spatsoc"))

# Cast the character column to POSIXct
DT[, datetime := as.POSIXct(datetime, tz = "UTC")]

# Temporal grouping
group_times(DT, datetime = "datetime", threshold = "20 minutes")

# Edge list generation
dist <- edge_dist(  
  DT,  
  threshold = 100,  
  id = 'ID',  
  coords = c('X', 'Y'),  
  timegroup = 'timegroup',  
  returnDist = TRUE,  
  fillNA = TRUE
)

```r
edge_nn

Nearest neighbour based edge lists

Description

data.nn returns edge lists defined by the nearest neighbour. The function accepts a data.table with relocation data, individual identifiers and a threshold argument. The threshold argument is used to specify the criteria for distance between points which defines a group. Relocation data should be in two columns representing the X and Y coordinates.
```
edge_nn

data.table

Usage

edge_nn(
        DT = NULL,
        id = NULL,
        coords = NULL,
        timegroup,
        splitBy = NULL,
        threshold = NULL,
        returnDist = FALSE
    )

Arguments

DT    input data.table
id    Character string of ID column name
coords Character vector of X coordinate and Y coordinate column names
timegroup timegroup field in the DT upon which the grouping will be calculated
splitBy (optional) character string or vector of grouping column name(s) upon which
         the grouping will be calculated
threshold (optional) spatial distance threshold to set maximum distance between an individual and their neighbour.
returnDist boolean indicating if the distance between individuals should be returned. If FALSE (default), only ID, NN columns (and timegroup, splitBy columns if provided) are returned. If TRUE, another column "distance" is returned indicating the distance between ID and NN.

Details

The DT must be a data.table. If your data is a data.frame, you can convert it by reference using data.table::setDT.

The id, coords (and optional timegroup and splitBy) arguments expect the names of a column in DT which correspond to the individual identifier, X and Y coordinates, timegroup (generated by group_times) and additional grouping columns.

The threshold must be provided in the units of the coordinates. The threshold must be larger than 0. The coordinates must be planar coordinates (e.g.: UTM). In the case of UTM, a threshold = 50 would indicate a 50m distance threshold.

The timegroup argument is optional, but recommended to pair with group_times. The intended framework is to group rows temporally with group_times then spatially with edge_nn (or grouping functions).

The splitBy argument offers further control over grouping. If within your DT, you have multiple populations, subgroups or other distinct parts, you can provide the name of the column which identifies them to splitBy. edge_nn will only consider rows within each splitBy subgroup.
**Value**

`edge_nn` returns a `data.table` with three columns: `timegroup`, `ID` and `NN`. If `returnDist` is TRUE, column `distance` is returned indicating the distance between `ID` and `NN`.

The `ID` and `NN` columns represent the edges defined by the nearest neighbours (and temporal thresholds with `group_times`).

If an individual was alone in a timegroup or `splitBy`, or did not have any neighbours within the threshold distance, they are assigned NA for nearest neighbour.

**See Also**

Other Edge-list generation: `edge_dist()`

**Examples**

```r
# Load data.table
library(data.table)

# Read example data
DT <- fread(system.file("extdata", "DT.csv", package = "spatsoc"))

# Cast the character column to POSIXct
DT[, datetime := as.POSIXct(datetime, tz = 'UTC')]}

# Temporal grouping
group_times(DT, datetime = 'datetime', threshold = '20 minutes')

# Edge list generation
distances <- edge_nn(DT, id = 'ID', coords = c('X', 'Y'),
                     timegroup = 'timegroup')

# Edge list generation using maximum distance threshold
distances <- edge_nn(DT, id = 'ID', coords = c('X', 'Y'),
                     timegroup = 'timegroup', threshold = 100)

# Edge list generation, returning distance between nearest neighbours
distances <- edge_nn(DT, id = 'ID', coords = c('X', 'Y'),
                     timegroup = 'timegroup', threshold = 100,
                     returnDist = TRUE)
```

---

**get_gbi**

*Generate group by individual matrix*

**Description**

get_gbi generates a group by individual matrix. The function accepts a `data.table` with individual identifiers and a group column. The group by individual matrix can then be used to build a network using `asnipe::get_network`.
Usage

get_gbi(DT = NULL, group = "group", id = NULL)

Arguments

- **DT**: input data.table
- **group**: Character string of group column (generated from one of spatsoc’s spatial grouping functions)
- **id**: Character string of ID column name

Details

The DT must be a data.table. If your data is a data.frame, you can convert it by reference using `data.table::setDT`.

The group argument expects the name of a column which corresponds to an integer group identifier (generated by spatsoc’s grouping functions).

The id argument expects the name of a column which corresponds to the individual identifier.

Value

get_gbi returns a group by individual matrix (columns represent individuals and rows represent groups).

Note that get_gbi is identical in function for turning the outputs of spatsoc into social networks as `asnipe::get_group_by_individual` but is more efficient thanks to `data.table::dcast`.

See Also

group_pts group_lines group_polys

Other Social network tools: randomizations()

Examples

```r
# Load data.table
library(data.table)

# Read example data
DT <- fread(system.file("extdata", "DT.csv", package = "spatsoc"))

# Cast the character column to POSIXct
DT[, datetime := as.POSIXct(datetime, tz = "UTC")]
DT[, yr := year(datetime)]

utm <- '+proj=utm +zone=36 +south +ellps=WGS84 +datum=WGS84 +units=m +no_defs'

group_polys(DT, area = FALSE, hrType = 'mcp',
            hrParams = list(percent = 95),
            projection = utm, id = 'ID', coords = c('X', 'Y'),
            splitBy = 'yr')
```
group_lines <- get_gbi(DT = DT, group = 'group', id = 'ID')

Description

group_lines groups rows into spatial groups by creating trajectories and grouping based on spatial overlap. The function accepts a data.table with relocation data, individual identifiers and a threshold. The relocation data is transformed into SpatialLines and overlapping SpatialLines are grouped. The threshold argument is used to specify the criteria for distance between lines. Relocation data should be in two columns representing the X and Y coordinates.

Usage

group_lines(
  DT = NULL,
  threshold = NULL,
  projection = NULL,
  id = NULL,
  coords = NULL,
  timegroup = NULL,
  sortBy = NULL,
  splitBy = NULL,
  spLines = NULL
)

Arguments

DT  input data.table
threshold  The width of the buffer around the lines in the units of the projection. Supply 0 to compare intersection without buffering.
projection  PROJ.4 character string
id  Character string of ID column name
coords  Character vector of X coordinate and Y coordinate column names
timegroup  timegroup field in the DT upon which the grouping will be calculated
sortBy  Character string of date time column(s) to sort rows by. Must be a POSIXct.
splitBy  (optional) character string or vector of grouping column name(s) upon which the grouping will be calculated
spLines  Alternatively to providing a DT, provide a SpatialLines object created with the sp package. If a spLines object is provided, groups cannot be calculated by a timegroup or splitBy.
Details

The DT must be a data.table. If your data is a data.frame, you can convert it by reference using `data.table::setDT`.

The id, coords, sortBy (and optional timegroup and splitBy) arguments expect the names of respective columns in DT which correspond to the individual identifier, X and Y coordinates, sorting, timegroup (generated by `group_times`) and additional grouping columns.

The sortBy is used to order the input data.table when creating SpatialLines. It must a POSIXct to ensure the rows are sorted by date time. The projection expects a PROJ.4 character string (such as those available on https://spatialreference.org/). `group_lines` expects planar coordinates (not unprojected latitude, longitude).

The threshold must be provided in the units of the coordinates. The threshold can be equal to 0 if strict overlap is required, else it needs to be greater than 0. The coordinates must be planar coordinates (e.g.: UTM). In the case of UTM, a threshold = 50 would indicate a 50m distance threshold.

The timegroup argument is optional, but recommended to pair with `group_times`. The intended framework is to group rows temporally with `group_times` then spatially with `group_lines` (or `group_polys`). With `group_lines`, pick a relevant `group_times` threshold such as '1 day' or '7 days' which is informed by your study species and system.

The splitBy argument offers further control over grouping. If within your DT, you have multiple populations, subgroups or other distinct parts, you can provide the name of the column which identifies them to splitBy. The grouping performed by `group_lines` will only consider rows within each splitBy subgroup.

Value

`group_lines` returns the input DT appended with a group column.

This column represents the spatial (and if timegroup was provided - spatiotemporal) group calculated by overlapping lines. As with the other grouping functions, the actual value of group is arbitrary and represents the identity of a given group where 1 or more individuals are assigned to a group. If the data was reordered, the group may change, but the contents of each group would not. A message is returned when a column named group already exists in the input DT, because it will be overwritten.

See Also

`build_lines`, `group_times`

Other Spatial grouping: `group_polys()`, `group_pts()`

Examples

```r
# Load data.table
library(data.table)

# Read example data
DT <- fread(system.file("extdata", "DT.csv", package = "spatsoc"))

# Subset only individuals A, B, and C
```
DT <- DT[ID %in% c('A', 'B', 'C')]

# Cast the character column to POSIXct
DT[, datetime := as.POSIXct(datetime, tz = 'UTC')]

# Proj4 string for example data
utm <- '+proj=utm +zone=36 +south +ellps=WGS84 +datum=WGS84 +units=m +no_defs'

group_lines(DT, threshold = 50, projection = utm, sortBy = 'datetime',
           id = 'ID', coords = c('X', 'Y'))

## Daily movement tracks
# Temporal grouping
group_times(DT, datetime = 'datetime', threshold = '1 day')

# Subset only first 50 days
DT <- DT[timegroup < 25]

# Spatial grouping
group_lines(DT, threshold = 50, projection = utm,
           id = 'ID', coords = c('X', 'Y'),
           timegroup = 'timegroup', sortBy = 'datetime')

## Daily movement tracks by population
group_lines(DT, threshold = 50, projection = utm,
           id = 'ID', coords = c('X', 'Y'),
           timegroup = 'timegroup', sortBy = 'datetime',
           splitBy = 'population')

group_polys

Description

group_polys groups rows into spatial groups by overlapping polygons (home ranges). The function accepts a data.table with relocation data, individual identifiers and an area argument. The relocation data is transformed into home range SpatialPolygons. If the area argument is FALSE, group_polys returns grouping calculated by overlap. If the area argument is TRUE, the area and proportion of overlap is calculated. Relocation data should be in two columns representing the X and Y coordinates.

Usage

```r
group_polys(
  DT = NULL,
  area = NULL,
  hrType = NULL,
  hrParams = NULL,
  projection = NULL,
)```
Arguments

DT input data.table
area boolean indicating either overlap group (when FALSE) or area and proportion of overlap (when TRUE)
hrType type of HR estimation, either 'mcp' or 'kernel'
hrParams a named list of parameters for adehabitatHR functions
projection PROJ.4 character string
id Character string of ID column name
coords Character vector of X coordinate and Y coordinate column names
splitBy (optional) character string or vector of grouping column name(s) upon which the grouping will be calculated
spPolys Alternatively, provide solely a SpatialPolygons object

Details

The DT must be a data.table. If your data is a data.frame, you can convert it by reference using data.table::setDT.

The id, coords (and optional splitBy) arguments expect the names of respective columns in DT which correspond to the individual identifier, X and Y coordinates, and additional grouping columns.

The projection expects a PROJ.4 character string (such as those available on https://spatialreference.org/). group_polys expects planar coordinates (not unprojected latitude, longitude).

The hrType must be either one of "kernel" or "mcp". The hrParams must be a named list of arguments matching those of adehabitatHR::kernelUD or adehabitatHR::mcp.

The splitBy argument offers further control over grouping. If within your DT, you have multiple populations, subgroups or other distinct parts, you can provide the name of the column which identifies them to splitBy. The grouping performed by group_polys will only consider rows within each splitBy subgroup.

Value

When area is FALSE, group_polys returns the input DT appended with a group column. As with the other grouping functions, the actual value of group is arbitrary and represents the identity of a given group where 1 or more individuals are assigned to a group. If the data was reordered, the group may change, but the contents of each group would not. When area is TRUE, group_polys returns a proportional area overlap data.table. In this case, ID refers to the focal individual of which the total area is compared against the overlapping area of ID2.

If area is FALSE, a message is returned when a column named group already exists in the input DT, because it will be overwritten.

# Cast the character column to POSIXct
DT[, datetime := as.POSIXct(datetime, tz = 'UTC')]

# Proj4 string for example data
utm <- '+proj=utm +zone=36 +south +ellps=WGS84 +datum=WGS84 +units=m +no_defs'

group_polys(DT, area = FALSE, 'mcp', list(percent = 95),
projection = utm,
id = 'ID', coords = c('X', 'Y'))

areaDT <- group_polys(DT, area = TRUE, 'mcp', list(percent = 95),
projection = utm,
id = 'ID', coords = c('X', 'Y'))

---

Description

group_pts groups rows into spatial groups. The function accepts a data.table with relocation
data, individual identifiers and a threshold argument. The threshold argument is used to specify
the criteria for distance between points which defines a group. Relocation data should be in two
columns representing the X and Y coordinates.

Usage

group_pts(
  DT = NULL,
  threshold = NULL,
  id = NULL,
  coords = NULL,
  timegroup,
  splitBy = NULL
)
Arguments

DT input data.table
threshold distance for grouping points, in the units of the coordinates
id Character string of ID column name
coords Character vector of X coordinate and Y coordinate column names
timegroup timegroup field in the DT upon which the grouping will be calculated
splitBy (optional) character string or vector of grouping column name(s) upon which the grouping will be calculated

Details

The DT must be a data.table. If your data is a data.frame, you can convert it by reference using `data.table::setDT`.

The id, coords (and optional timegroup and splitBy) arguments expect the names of a column in DT which correspond to the individual identifier, X and Y coordinates, timegroup (generated by `group_times`) and additional grouping columns.

The threshold must be provided in the units of the coordinates. The threshold must be larger than 0. The coordinates must be planar coordinates (e.g.: UTM). In the case of UTM, a threshold = 50 would indicate a 50m distance threshold.

The timegroup argument is optional, but recommended to pair with `group_times`. The intended framework is to group rows temporally with `group_times` then spatially with `group_pts` (or `group_lines`, `group_polys`).

The splitBy argument offers further control over grouping. If within your DT, you have multiple populations, subgroups or other distinct parts, you can provide the name of the column which identifies them to splitBy. The grouping performed by `group_pts` will only consider rows within each splitBy subgroup.

Value

`group_pts` returns the input DT appended with a group column.

This column represents the spatial (and if timegroup was provided - spatiotemporal) group. As with the other grouping functions, the actual value of group is arbitrary and represents the identity of a given group where 1 or more individuals are assigned to a group. If the data was reordered, the group may change, but the contents of each group would not.

A message is returned when a column named group already exists in the input DT, because it will be overwritten.

Examples

# Load data.table
library(data.table)

# Read example data
DT <- fread(system.file("extdata", "DT.csv", package = "spatsoc"))

# Cast the character column to POSIXct
DT[, datetime := as.POSIXct(datetime, tz = "UTC")]

# Temporal grouping
group_times(DT, datetime = 'datetime', threshold = '20 minutes')

# Spatial grouping with timegroup
group_pts(DT, threshold = 5, id = 'ID', 
          coords = c('X', 'Y'), timegroup = 'timegroup')

# Spatial grouping with timegroup and splitBy on population
group_pts(DT, threshold = 5, id = 'ID', coords = c('X', 'Y'), 
          timegroup = 'timegroup', splitBy = 'population')

---

### group_times

**Description**

group_times groups rows into time groups. The function accepts date time formatted data and a threshold argument. The threshold argument is used to specify a time window within which rows are grouped.

**Usage**

group_times(DT = NULL, datetime = NULL, threshold = NULL)

**Arguments**

- **DT**: input data.table
- **datetime**: name of date time column(s). either 1 POSIXct or 2 IDate and ITime. e.g.: 'datetime' or c('idate', 'itime')
- **threshold**: threshold for grouping times. e.g.: '2 hours', '10 minutes', etc. if not provided, times will be matched exactly. Note that provided threshold must be in the expected format: '# unit'
Details

The DT must be a data.table. If your data is a data.frame, you can convert it by reference using data.table::setDT.

The datetime argument expects the name of a column in DT which is of type POSIXct or the name of two columns in DT which are of type IDate and ITime.

threshold must be provided in units of minutes, hours or days. The character string should start with an integer followed by a unit, separated by a space. It is interpreted in terms of 24 hours which poses the following limitations:

- minutes, hours and days cannot be fractional
- minutes must divide evenly into 60
- minutes must not exceed 60
- minutes, hours which are nearer to the next day, are grouped as such
- hours must divide evenly into 24
- multi-day blocks should divide into the range of days, else the blocks may not be the same length

In addition, the threshold is considered a fixed window throughout the time series and the rows are grouped to the nearest interval.

If threshold is NULL, rows are grouped using the datetime column directly.

Value

group_times returns the input DT appended with a timegroup column and additional temporal grouping columns to help investigate, troubleshoot and interpret the timegroup.

The actual value of timegroup is arbitrary and represents the identity of a given timegroup which 1 or more individuals are assigned to. If the data was reordered, the group may change, but the contents of each group would not.

The temporal grouping columns added depend on the threshold provided:

- threshold with unit minutes: "minutes" column added identifying the nearest minute group for each row.
- threshold with unit hours: "hours" column added identifying the nearest hour group for each row.
- threshold with unit days: "block" columns added identifying the multiday block for each row.

A message is returned when any of these columns already exist in the input DT, because they will be overwritten.

**Examples**

```r
# Load data.table
library(data.table)

# Read example data
DT <- fread(system.file("extdata", "DT.csv", package = "spatsoc"))

# Cast the character column to POSIXct
DT[, datetime := as.POSIXct(datetime, tz = "UTC")]

group_times(DT, datetime = "datetime", threshold = "5 minutes")
group_times(DT, datetime = "datetime", threshold = "2 hours")
group_times(DT, datetime = "datetime", threshold = "10 days")
```

---

### randomizations

**Data-stream randomizations**

**Description**

randomizations performs data-stream social network randomization. The function accepts a data.table with relocation data, individual identifiers and a randomization type. The data.table is randomized either using step or daily between-individual methods, or within-individual daily trajectory method described by Spiegel et al. (2016).

**Usage**

```r
randomizations(
  DT = NULL,
  type = NULL,
  id = NULL,
  group = NULL,
  coords = NULL,
  datetime = NULL,
  splitBy = NULL,
  iterations = NULL
)
```

**Arguments**

- **DT**: input data.table
- **type**: one of 'daily', 'step' or 'trajectory' - see details
- **id**: Character string of ID column name
- **group**: generated from spatial grouping functions - see details
- **coords**: Character vector of X coordinate and Y coordinate column names
randomizations

datetime field used for providing date time or time group - see details
splitBy List of fields in DT to split the randomization process by
iterations The number of iterations to randomize

Details

The DT must be a data.table. If your data is a data.frame, you can convert it by reference using data.table::setDT.

Three randomization types are provided:

1. step - randomizes identities of relocations between individuals within each time step.
2. daily - randomizes identities of relocations between individuals within each day.
3. trajectory - randomizes daily trajectories within individuals (Spiegel et al. 2016).

Depending on the type, the datetime must be a certain format:

- step - datetime is integer group created by group_times
- daily - datetime is POSIXct format
- trajectory - datetime is POSIXct format

The id, datetime, (and optional splitBy) arguments expect the names of respective columns in DT which correspond to the individual identifier, date time, and additional grouping columns. The coords argument is only required when the type is "trajectory", since the coordinates are required for recalculating spatial groups with group_pts, group_lines or group_polys.

Please note that if the data extends over multiple years, a column indicating the year should be provided to the splitBy argument. This will ensure randomizations only occur within each year.

The group argument is expected only when type is 'step' or 'daily'.

For example, using data.table::year:

```r
dT[, yr := year(datetime)] randomizations(DT, type = 'step',
id = 'ID', datetime = 'timegroup', splitBy = 'yr')
```

iterations is set to 1 if not provided. Take caution with a large value for iterations with large input DT.

Value

randomizations returns the random date time or random id along with the original DT, depending on the randomization type. The length of the returned data.table is the original number of rows multiplied by the number of iterations + 1. For example, 3 iterations will return 4x - one observed and three randomized.

Two columns are always returned:

- observed - if the rows represent the observed (TRUE/FALSE)
- iteration - iteration of rows (where 0 is the observed)
randomizations

In addition, depending on the randomization type, random ID or random date time columns are returned:

- **step** - randomID each time step
- **daily** - randomID for each day and jul indicating julian day
- **trajectory** - a random date time ("random" prefixed to datetime argument), observed jul and randomJul indicating the random day relocations are swapped to.

Examples

```r
# Load data.table
library(data.table)

# Read example data
DT <- fread(system.file("extdata", "DT.csv", package = "spatsoc"))

# Date time columns
DT[, datetime := as.POSIXct(datetime)]
DT[, yr := year(datetime)]

# Temporal grouping
group_times(DT, datetime = 'datetime', threshold = '5 minutes')

group_pts(DT, threshold = 5, id = 'ID', coords = c('X', 'Y'), timegroup = 'timegroup')

# Randomization: step
randStep <- randomizations(DT,
    type = 'step',
    id = 'ID',
    group = 'group',
    datetime = 'timegroup',
    splitBy = 'yr',
    iterations = 2)

# Randomization: daily
randDaily <- randomizations(DT,
    type = 'daily',
    id = 'ID',
    group = 'group',
    datetime = 'datetime',
    splitBy = 'yr',
    iterations = 2)
```

spatsoc

splitBy = 'yr',
iterations = 2
)

# Randomization: trajectory
randTraj <- randomizations(
  DT,
  type = 'trajectory',
  id = 'ID',
  group = NULL,
  coords = c('X', 'Y'),
  datetime = 'datetime',
  splitBy = 'yr',
  iterations = 2
)

spatsoc

Description

spatsoc is an R package for detecting spatial and temporal groups in GPS relocations. It can be used to convert GPS relocations to gambit-of-the-group format to build proximity-based social networks. In addition, the randomization function provides data-stream randomization methods suitable for GPS data.

Details

The spatsoc package provides one temporal grouping function:

- **group_times**

three spatial grouping functions:

- **group_pts**
- **group_lines**
- **group_polys**

two edge list generating functions:

- **edge_dist**
- **edge_nn**

and two social network functions:

- **randomizations**
- **get_gbi**
