Package ‘vapour’

October 7, 2021

Title Lightweight Access to the ‘Geospatial Data Abstraction Library’
(‘GDAL’)

Version 0.8.5

Description Provides low-level access to ‘GDAL’ functionality for R packages.
‘GDAL’ is the ‘Geospatial Data Abstraction Library’ a translator for raster and vector geospatial data formats
that presents a single raster abstract data model and single vector abstract data model to the calling application
for all supported formats <https://gdal.org/>.

Depends R (>= 3.3.0)

License GPL-3

Encoding UTF-8

LazyData true

LinkingTo Rcpp

Imports Rcpp, utils

RoxygenNote 7.1.2

Suggests testthat, knitr, markdown, rmarkdown, spelling

SystemRequirements GDAL (>= 2.0.1), PROJ.4 (>= 4.8.0), C++11

Index 33
Description

A lightweight GDAL API package for R.

Details

Provides low-level access to 'GDAL' functionality for R packages. The aim is to minimize the level of interpretation put on the 'GDAL' facilities, to enable direct use of it for a variety of purposes. 'GDAL' is the 'Geospatial Data Abstraction Library' a translator for raster and vector geospatial data formats that presents a single raster abstract data model and single vector abstract data model to the calling application for all supported formats https://gdal.org/.

Lightweight means we access parts of the GDAL API as near as possible to their native usage. GDAL is not a lightweight library, but provide a very nice abstraction over format details for a very large number of different formats.

Functions for raster and vector sources are included.

```r
# vapour-driver
vapour_all_drivers list of all available drivers, with type and features
vapour_driver report short name of driver that will be used for a data source
vapour_gdal_version report version of GDAL in use
vapour_srs_wkt produce WKT projection string from various projection string inputs
vapour_vsi_list report contents of VSI sources

vapour_raster_gcp return internal ground control points, if present
vapour_raster_info structural metadata of a source
vapour_read_raster read data direct from a window of a raster band source
vapour_sds_names list individual raster sources in a source containing subdatasets
vapour_warp_raster read data direct from a raster source into a specific window

vapour_driver report name of the driver used for a given source
vapour_geom_name report attribute name of geometry
vapour_geom_summary report simple properties of each feature geometry
vapour_layer_names list names of vector layers in a data source
vapour_layer_info list of data source, driver, layer name/s, fields, feature count, projection
vapour_read_extent read the extent, or bounding box, of geometries in a layer
vapour_read_fields read attributes of features in a layer, the columnar data associated with each geometry
vapour_read_geometry read geometry in binary (blob, WKB) form
vapour_read_geometry_ia read geometry by index, arbitrary
vapour_read_geometry_ij read geometry by sequential index, i to j
```
As far as possible vapour aims to minimize the level of interpretation provided for the functions, so that developers can choose how things are implemented. Functions return raw lists or vectors rather than data frames or classed types.

### sst_c  
**SST contours**

**Description**
Southern Ocean GHRSST contours in sf data frame from 2017-07-28, read from

**Details**

See data-raw/sst_c.R for the derivation column sst_c in Celsius.

Also stored in GeoPackage format in system.file("extdata/sst_c.gpkg",package = "vapour")

**Examples**
```r
## library(sf)
## plot(sst_c)

f <- system.file("extdata/sst_c.gpkg", package = "vapour")

## create an equivalent but class-less form of sst_c with GeoJSON rather than sf sfc format
atts <- vapour_read_fields(f)
dat <- as.data.frame(atts, stringsAsFactors = FALSE)
dat["json"] <- vapour_read_geometry_text(f)
names(dat)
names(sst_c)
```

### tas_wkt  
**Example WKT coordinate reference system**

**Description**
A Lambert Azimuthal Equal Area Well-Known-Text string for a region centred on Tasmania.

**Details**
Created from '+proj=laea +lon_0=147 +lat_0=-42 +datum=WGS84'. For use in a future warping example.
vapour_gdal_version

---

vapour_gdal_version  GDAL version and drivers.

Description

Return information about the GDAL library in use.

Usage

vapour_gdal_version()
vapour_all_drivers()
vapour_driver(dsource)

Arguments

dsource  data source string (i.e. file name or URL or database connection string)

Details

vapour_gdal_version returns the version of GDAL as a string. This corresponds to the "–version" as described for "GDALVersionInfo". GDAL documentation.

vapour_all_drivers returns the names and capabilities of all available drivers, in a list. This contains:

- driver the driver (short) name
- name the (long) description name
- vector logical vector indicating a vector driver
- raster logical vector indicating a raster driver
- create driver can create (note vapour provides no write capacity)
- copy driver can copy (note vapour provides no write capacity)
- virtual driver has virtual capabilities ('vsi')

vapour_driver() returns the short name of the driver, e.g. 'GPKG' or 'GTiff', to get the long name and other properties use vapour_all_drivers() and match on 'driver'.

Value

please see Details, character vectors or lists of character vectors
Examples

vapour_gdal_version()

drv <- vapour_all_drivers()

f <- system.file("extdata/sst_c.gpkg", package = "vapour")
vapour_driver(f)

as.data.frame(drv)[match(vapour_driver(f), drv$driver), ]

---

vapour_geom_name: Read geometry column name

Description

There might be one or more geometry column names, or it might be an empty string.

Usage

vapour_geom_name(dsource, layer = 0L, sql = "")

Arguments

dsource: data source name (path to file, connection string, URL)
layer: integer of layer to work with, defaults to the first (0) or the name of the layer
sql: if not empty this is executed against the data source (layer will be ignored)

Details

It might be ":", or "geom", or "ogr_geometry" - the last is a default name given when SQL is executed by GDAL but there was no geometry name, and 'SELECT * ' or equivalent was used.

This feature is required by the DBI backend work in RGDALSQL, so that when SELECT * is used we can give a reasonable name to the geometry column which is obtained separately.

Value

character vector of geometry column name/s

Examples

file <- system.file("extdata/tab/list_locality_postcode_meander_valley.tab", package = "vapour")
vapour_geom_name(file)  ## empty string
vapour_geom_summary

Summary of available geometry

Description
Read properties of geometry from a source, optionally after SQL execution.

Usage
vapour_geom_summary(
  dsource,
  layer = 0L,
  sql = "",
  limit_n = NULL,
  skip_n = 0,
  extent = NA
)

Arguments
dsource  data source name (path to file, connection string, URL)
layer  integer of layer to work with, defaults to the first (0) or the name of the layer
sql  if not empty this is executed against the data source (layer will be ignored)
limit_n  an arbitrary limit to the number of features scanned
skip_n  an arbitrary number of features to skip
extent  apply an arbitrary extent, only when 'sql' used (must be 'ex = c(xmin, xmax, ymin, ymax)' but sp bbox, sf bbox, and raster extent also accepted)

Details
Use limit_n to arbitrarily limit the number of features queried.

Value
list containing the following

- FID the feature id value (an integer, usually sequential)
- valid_geometry logical value if a non-empty geometry is available
- type integer value of geometry type from GDAL enumeration
- xmin, xmax, ymin, ymax numeric values of the extent (bounding box) of each geometry
**Examples**

```r
file <- "list_locality_postcode_meander_valley.tab"
mvfile <- system.file(file.path("extdata/tab", file), package="vapour")
vapour_geom_summary(mvfile, limit_n = 3L)

gsum <- vapour_geom_summary(mvfile)
plot(NA, xlim = range(c(gsum$xmin, gsum$xmax), na.rm = TRUE),
     ylim = range(c(gsum$ymin, gsum$ymax), na.rm = TRUE))
rect(gsum$xmin, gsum$ymin, gsumxmax, gsum$ymax)
text(gsum$xmin, gsum$ymin, labels = gsum$FID)
```

---

**vapour_layer_info**  
*Read GDAL layer info*

**Description**

Read GDAL layer information for a vector data source.

**Usage**

```r
vapour_layer_info(
  dsource,
  layer = 0L,
  sql = "",
  ...,
  extent = TRUE,
  count = TRUE
)
```

**Arguments**

- **dsourc**e: data source name (path to file, connection string, URL)
- **layer**: integer of layer to work with, defaults to the first (0) or the name of the layer
- **sql**: if not empty this is executed against the data source (layer will be ignored)
- **...**: unused, reserved for future use
- **extent**: logical to control if extent calculated and returned, TRUE by default (set to FALSE to avoid the extra calculation and missing value is the result)
- **count**: logical to control if count calculated and returned, TRUE by default (set to FALSE to avoid the extra calculation and missing value is the result)

**Details**

Set extent and/or count to FALSE to avoid calculating them if not needed, it might take some time.

The layer information elements are

- **dsn**: the data source name
**vapour_layer_names**

**Description**

Obtain the names of available layers from a GDAL vector source.

**Usage**

vapour_layer_names(dsourse, ...)

**Arguments**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dsourse</td>
<td>data source name (path to file, connection string, URL)</td>
</tr>
<tr>
<td>...</td>
<td>arguments ignore for deprecated compatibility (no 'sql' argument any longer)</td>
</tr>
</tbody>
</table>
Details

Some vector sources have multiple layers while many have only one. Shapefiles for example have only one, and the single layer gets the file name with no path and no extension. GDAL provides a quirk for shapefiles in that a directory may act as a data source, and any shapefile in that directory acts like a layer of that data source. This is a little like the one-or-many sleight that exists for raster data sources with subdatasets (there’s no way to virtualize single rasters into a data source with multiple subdatasets, oh except by using VRT....)

See vapour_sds_names for more on the multiple topic.

Value

character vector of layer names

Examples

```r
file <- "list_locality_postcode_meander_valley.tab"
mvfile <- system.file(file.path("extdata/tab", file), package="vapour")
vapour_layer_names(mvfile)
```

vapour_raster_gcp  Raster ground control points

Description

Return any ground control points for a raster data set, if they exist.

Usage

```r
vapour_raster_gcp(x, ...)
```

Arguments

- `x`: data source string (i.e. file name or URL or database connection string)
- `...`: ignored currently

Details

Pixel and Line coordinates do not correspond to cells in the underlying raster grid, they refer to the index space of that array in 0, ncols and 0, nrows. They are usually a subsample of the grid and may not align with the grid spacing itself (though they often do in satellite remote sensing products).

The coordinate system of the GCPs is currently not read.
Value

list with

- Pixel the pixel coordinate
- Line the line coordinate
- X the X coordinate of the GCP
- Y the Y coordinate of the GCP
- Z the Z coordinate of the GCP (usually zero)

Examples

```r
## this file has no ground control points
## they are rare, and tend to be in large files
f <- system.file("extdata", "sst.tif", package = "vapour")
vapour_raster_gcp(f)

## a very made-up example with no real use
f1 <- system.file("extdata/gcps", "volcano_gcp.tif", package = "vapour")
vapour_raster_gcp(f1)
```

Description

Return the basic structural metadata of a raster source understood by GDAL. Subdatasets may be specified by number, starting at 1. See `vapour_sds_names` for more.

Usage

`vapour_raster_info(x, ..., sds = NULL, min_max = FALSE)`

Arguments

- `x` data source string (i.e. file name or URL or database connection string)
- `...` currently unused
- `sds` a subdataset number, if necessary
- `min_max` logical, control computing min and max values in source (’FALSE’ by default)
Details

The structural metadata are

- **extent** the extent of the data, xmin, xmax, ymin, ymax - these are the lower left and upper right corners of pixels
- **geotransform** the affine transform
- **dimXY** dimensions x-y, columns*rows
- **minmax** numeric values of the computed min and max from the first band (optional)
- **tilesXY** dimensions x-y of internal tiling scheme
- **projection** text version of map projection parameter string
- **bands** number of bands in the dataset
- **projstring** the proj string version of `projection`
- **nodata_value** not implemented
- **overviews** the number and size of any available overviews
- **filelist** the list of files involved (may be none, and so will be a single NA character value)
- **datatype** the band type name, in GDAL form 'Byte', 'Int16', 'Float32', etc.

Note that the geotransform is a kind of obscure combination of the extent and dimension, I don’t find it useful and modern GDAL is moving away from needing it so much. Extent is more sensible and used in many places in a straightforward way.

On access vapour functions will report on the existence of subdatasets while defaulting to the first subdataset found.

Value

list with vectors 'geotransform', 'dimXY', 'minmax', 'tilesXY', 'projection', 'bands', 'proj4', 'nodata_value', 'overviews', 'filelist' see sections in Details for more on each element

Subdatasets

Some sources provide multiple data sets, where a dataset is described by a 2- (or more) dimensional grid whose structure is described by the metadata described above. Note that subdataset is a different concept to band or dimension. Sources that may have multiple data sets are HDF4/HDF5 and NetCDF, and they are loosely analogous to the concept of layer in GDAL vector data. Variables are usually seen as distinct data but in GDAL and related 2D-interpretations this concept is leveraged as a 3rd dimension (and higher). In a GeoTIFF a third dimension might be implicit across bands, i.e. to express time varying data and so each band is not properly a variable. Similarly in NetCDF, the data may be any dimensional but there’s only an implicit link for other variables that exist in that same dimensional space. When using GDAL you are always traversing this confusing realm.

If subdatasets are present but not specified the first is queried. The choice of subdataset is analogous to the way that the raster package behaves, and uses the argument varname. Variables in NetCDF correspond to subdatasets, but a single data set might have multiple variables in different bands or in dimensions, so this guide does not hold across various systems.
The Geo Transform

From https://gdal.org/user/raster_data_model.html.

The affine transform consists of six coefficients returned by GDALDataset::GetGeoTransform() which map pixel/line coordinates into georeferenced space using the following relationship:

$$X_{geo} = GT(0) + X_{pixel} \times GT(1) + Y_{line} \times GT(2)$$

$$Y_{geo} = GT(3) + X_{pixel} \times GT(4) + Y_{line} \times GT(5)$$

They are

GT0, xmin the x position of the lower left corner of the lower left pixel

GT1, xres the scale of the x-axis, the width of the pixel in x-units

GT2, yskew y component of the pixel width

GT3, ymax the y position of the upper left corner of the upper left pixel

GT4, xskew x component of the pixel height

GT5, yres the scale of the y-axis, the height of the pixel in negative y-units

Please note that these coefficients are equivalent to the contents of a world file but that the order is not the same and the world file uses cell centre convention rather than edge. https://en.wikipedia.org/wiki/World_file

Usually the skew components are zero, and so only four coefficients are relevant and correspond to the offset and scale used to position the raster - in combination with the number of rows and columns of data they provide the spatial extent and the pixel size in each direction. Very rarely a an actual affine raster will be use with this rotation specified within the transform coefficients.

Calculation of 'minmax' can take a significant amount of time, so it's not done by default. Use 'minmax = TRUE' to do it. (It does perform well, but may be prohibitive for very large or remote sources.)

Overviews

If there are no overviews this element will simply be a single-element vector of value 0. If there are overviews, the first value will give the number of overviews and their dimensions will be listed as pairs of x,y values.

See Also

vapour_sds_info

Examples

f <- system.file("extdata", "sst.tif", package = "vapour")

vapour_raster_info(f)
vapour_read_fields  Read feature field data

Description

Read features fields (attributes), optionally after SQL execution.

Usage

vapour_read_fields(dsource, layer = 0L, sql = "", limit_n = NULL, skip_n = 0, extent = NA)

vapour_read_attributes(dsource, layer = 0L, sql = "", limit_n = NULL, skip_n = 0, extent = NA)

Arguments

dsource  data source name (path to file, connection string, URL)
layer  integer of layer to work with, defaults to the first (0) or the name of the layer
sql  if not empty this is executed against the data source (layer will be ignored)
limit_n  an arbitrary limit to the number of features scanned
skip_n  an arbitrary number of features to skip
extent  apply an arbitrary extent, only when 'sql' used (must be 'ex = c(xmin, xmax, ymin, ymax)' but sp bbox, sf bbox, and raster extent also accepted)

Details

Internal types are not fully supported, there are straightforward conversions for numeric, integer (32-bit) and string types. Date, Time, DateTime are returned as character, and Integer64 is returned as numeric.
Examples

```r
file <- "list_locality_postcode_meander_valley.tab"
mvfile <- system.file(file.path("extdata/tab", file), package="vapour")
att <- vapour_read_fields(mvfile)
str(att)

sq <- "SELECT * FROM list_locality_postcode_meander_valley WHERE FID < 5"
(att <- vapour_read_fields(mvfile, sql = sq))
pfile <- "list_locality_postcode_meander_valley.tab"
dsource <- system.file(file.path("extdata/tab", pfile), package="vapour")
SQL <- "SELECT NAME FROM list_locality_postcode_meander_valley WHERE POSTCODE < 7300"
vapour_read_fields(dsource, sql = SQL)
```

vapour_read_geometry

**Read GDAL feature geometry**

Description

Read GDAL geometry as binary blob, text, or numeric extent.

Usage

```r
vapour_read_geometry_ia(dsource, layer = 0L, sql = "", extent = NA, ia = NULL)
vapour_read_geometry_ij(dsource, layer = 0L, sql = "", extent = NA, ij = NULL)
vapour_read_geometry(dsource, layer = 0L, sql = "", extent = NA, skip_n = 0, limit_n = NULL, extent = NA)
vapour_read_geometry_text(dsource, layer = 0L, sql = "", textformat = "json", extent = NA, limit_n = NULL, skip_n = 0, extent = NA)
vapour_read_extent(dsource, layer = 0L)
```
vapour_read_geometry

sql = "",  
limit_n = NULL,  
skip_n = 0,  
extent = NA
)

vapour_read_type(  
dsource,  
layer = 0L,  
sql = "",  
limit_n = NULL,  
skip_n = 0,  
extent = NA
)

Arguments

dsource  data source name (path to file, connection string, URL)
layer    integer of layer to work with, defaults to the first (0) or the name of the layer
sql      if not empty this is executed against the data source (layer will be ignored)
extent   apply an arbitrary extent, only when 'sql' used (must be 'ex = c(xmin, xmax, ymin, ymax)' but sp bbox, sf bbox, and raster extent also accepted)
ia       an arbitrary index, integer vector with values between 0 and one less the number of features, duplicates allowed and arbitrary order is ok
ij        an range index, integer vector of length two with values between 0 and one less the number of features, this range of geometries is returned
limit_n  an arbitrary limit to the number of features scanned
skip_n   an arbitrary number of features to skip
textformat indicate text output format, available are "json" (default), "gml", "kml", "wkt"

Details

vapour_read_geometry will read features as binary WKB, vapour_read_geometry_text as various text formats (geo-json, wkt, kml, gml), vapour_read_extent a numeric extent which is the native bounding box, the four numbers (in this order) xmin, xmax, ymin, ymax. For each function an optional SQL string will be evaluated against the data source before reading.

vapour_read_geometry_cpp will read a feature for each of the ways listed above and is used by those functions. It’s recommended to use the more specialist functions rather than this more general one.

vapour_read_geometry_ia will read features by arbitrary index, so any integer between 0 and one less than the number of features. These may be duplicated. If 'ia' is greater than the highest index NULL is returned, but if less than 0 the function will error.

vapour_read_geometry_ij will read features by index range, so two numbers to read ever feature between those limits inclusively. 'i' and 'j' must be increasing.
vapour_read_names will read the (wkb) type of the geometry as an integer. These are 0 unknown, 1 Point, 2 LineString, 3 Polygon, 4 MultiPoint, 5 MultiLineString, 6 MultiPolygon, 7 GeometryCollection, and the other more exotic types listed in "api/vector_c_api.html" from the GDAL home page (as at October 2020).

Note that limit_n and skip_n interact with the affect of sql, first the query is executed on the data source, then while looping through available features skip_n features are ignored, and then a feature-count begins and the loop is stopped if limit_n is reached.

Note that extent applies to the 'SpatialFilter' of 'ExecuteSQL': https://gdal.org/user/ogr_sql_dialect.html#executesql.

Examples

```r
file <- "list_locality_postcode_meander_valley.tab"
## A MapInfo TAB file with polygons
mvfile <- system.file(file.path("extdata/tab", file), package="vapour")
## A shapefile with points
pfile <- system.file("extdata/point.shp", package = "vapour")

## raw binary WKB points in a list
ptgeom <- vapour_read_geometry(pfile)
## create a filter query to ensure data read is small
SQL <- "SELECT FID FROM list_locality_postcode_meander_valley WHERE FID < 3"
## polygons in raw binary (WKB)
plgeom <- vapour_read_geometry_text(mvfile, sql = SQL)
## polygons in raw text (GeoJSON)
txtjson <- vapour_read_geometry_text(mvfile, sql = SQL)

## polygon extents in a list xmin, xmax, ymin, ymax
exgeom <- vapour_read_extent(mvfile)

## points in raw text (GeoJSON)
txtpointjson <- vapour_read_geometry_text(pfile)
## points in raw text (WKT)
txtpointwkt <- vapour_read_geometry_text(pfile, textformat = "wkt")
```

vapour_read_names

**Read feature names**

**Description**

Obtains the internal 'Feature ID (FID)' for a data source.

**Usage**

```r
vapour_read_names(
  dsource,
  layer = 0L,
  sql = "",
  limit_n = NULL,
)```
skip_n = 0,
extent = NA
)

Arguments

dsource            data source name (path to file, connection string, URL)
layer              integer of layer to work with, defaults to the first (0) or
                   the name of the layer
sql                if not empty this is executed against the data source
                   (layer will be ignored)
limit_n            an arbitrary limit to the number of features scanned
skip_n             an arbitrary number of features to skip
extent             apply an arbitrary extent, only when 'sql' used (must
                   be 'ex = c(xmin, xmax, ymin, ymax)' but sp bbox, sf bbox, and
                   raster extent also accepted)

Details

This may be virtual (created by GDAL for the SQL interface) and may be 0- or 1- based. Some
drivers have actual names, and they are persistent and arbitrary. Please use with caution, this func-
tion can return the current FIDs, but there's no guarantee of what it represents for subsequent access.

An earlier version use 'OGRSQL' to obtain these names, which was slow for some drivers and also
clashed with independent use of the sql argument.

Value

character vector of geometry id 'names'

Examples

file <- "list_locality_postcode_meander_valley.tab"
mvfile <- system.file(file.path("extdata/tab", file), package="vapour")
range(fids <- vapour_read_names(mvfile))
length(fids)

vapour_read_raster    Raster IO (read)

Description

Read a window of data from a GDAL raster source. The first argument is the source name and the
second is a 6-element window of offset, source dimension, and output dimension.
vapour_read_raster

Usage

vapour_read_raster(
  x,
  band = 1,
  window,
  resample = "nearestneighbour",
  ..., 
  sds = NULL,
  native = FALSE,
  set_na = TRUE,
  band_output_type = ""
)

Arguments

x    data source
band index of which band to read (1-based)
window src_offset, src_dim, out_dim
resample resampling method used (see details)
...    reserved
sds    index of subdataset to read (usually 1)
native apply the full native window for read, FALSE by default
set_na specify whether NA values should be set for the NODATA
band_output_type numeric type of band to apply (else the native type if ")", is mapped to one of
            'Byte', 'Int32', or 'Float64'

Details

The value of window may be input as only 4 elements, in which case the source dimension will be used as the output dimension.

This is analogous to the rgdal function readGDAL with its arguments offset, region.dim and output.dim. There’s no semantic wrapper for this in vapour, but see https://github.com/hypertidy/lazyraster for one approach.

Resampling options will depend on GDAL version, but currently ‘NearestNeighbour’ (default), ‘Average’, ‘Bilinear’, ‘Cubic’, ‘CubicSpline’, ‘Gauss’, ‘Lanczos’, ‘Mode’ are potentially available. These are compared internally by converting to lower-case. Detailed use of this is barely tried or tested with vapour, but is a standard facility used in GDAL. Easiest way to compare results is with gdal_translate.

There is no write support in vapour.

Currently the window argument is required. If this argument unspecified and native = TRUE then the default window specification will be used, the entire extent at native resolution. If ‘window’ is specified and native = TRUE then the window is used as-is, with a warning (native is ignored).

‘band_output_type’ can be ‘raw’, ‘integer’, ‘double’, or case-insensitive versions of the GDAL types ‘Byte’, ‘UInt16’, ‘Int16’, ‘UInt32’, ‘Int32’, ‘Float32’, or ‘Float64’. These are mapped to one of the supported types ‘Byte’ (‘== raw’), ‘Int32’ (‘== integer’), or ‘Float64’ (‘== double’).
vapour_read_raster_block

Read or write raster block

Description
Read a 'block' from raster.

Usage
vapour_read_raster_block(
  dsourcename,  
  offset,  
  dimension,  
  band = 1L,  
  band_output_type = ""    
)

Arguments

  dsource file name to read from, or write to
  offset position x,y to start writing (0-based, y-top)
  dimension window size to read from, or write to
  band which band to read (1-based)
  band_output_type numeric type of band to apply (else the native type if ") can be one of 'Byte', 'Int32', or 'Float64'

Value
for vapour_read_raster_block, a list with vector of data
Examples

f <- system.file("extdata", "sst.tif", package = "vapour")
v <- vapour_read_raster_block(f, c(0L, 0L), dimension = c(2L, 3L), band = 1L)

---

type safe(r) raster read

Description

These wrappers around vapour_read_raster() guarantee single vector output of the nominated type.

Usage

vapour_read_raster_raw(
  x,
  band = 1,
  window,
  resample = "nearestneighbour",
  ..., 
  sds = NULL,
  native = FALSE,
  set_na = TRUE
)

vapour_read_raster_int(
  x,
  band = 1,
  window,
  resample = "nearestneighbour",
  ..., 
  sds = NULL,
  native = FALSE,
  set_na = TRUE
)

vapour_read_raster_dbl(
  x,
  band = 1,
  window,
  resample = "nearestneighbour",
  ..., 
  sds = NULL,
  native = FALSE,
  set_na = TRUE
)
vapour_read_raster_chr(
  x,
  band = 1,
  window,
  resample = "nearestneighbour",
  ..., 
  sds = NULL,
  native = FALSE,
  set_na = TRUE 
)

vapour_read_raster_hex(
  x,
  band = 1,
  window,
  resample = "nearestneighbour",
  ..., 
  sds = NULL,
  native = FALSE,
  set_na = TRUE 
)

Arguments

- **x**: data source
- **band**: index of which band to read (1-based)
- **window**: src_offset, src_dim, out_dim
- **resample**: resampling method used (see details)
- **...**: reserved
- **sds**: index of subdataset to read (usually 1)
- **native**: apply the full native window for read, FALSE by default
- **set_na**: specify whether NA values should be set for the NODATA

Details

_hex and _chr are aliases of each other.

Value

atomic vector of the nominated type raw, int, dbl, or character (hex)

Examples

```r
f <- system.file("extdata", "sst.tif", package = "vapour")
vapour_read_raster_int(f, window = c(0, 0, 5, 4))
vapour_read_raster_raw(f, window = c(0, 0, 5, 4))
vapour_read_raster_chr(f, window = c(0, 0, 5, 4))
```
vapour_report_fields

plot(vapour_read_raster_dbl(f, native = TRUE), pch = ",", ylim = c(273, 300))

vapour_report_fields  Read feature field types.

Description

Obtains the internal type-constant name for the data attributes in a source.

Usage

vapour_report_fields(dsource, layer = 0L, sql = "")

vapour_report_attributes(dsource, layer = 0L, sql = ")"

Arguments

dsource data source name (path to file, connection string, URL)
layer integer of layer to work with, defaults to the first (0) or the name of the layer
sql if not empty this is executed against the data source (layer will be ignored)

Details

Use this to compare the interpreted versions converted into R types by vapour_read_fields.

This and vapour_read_fields() are aliased to older versions named 'vapour_report_attributes()' and 'vapour_read_attributes()', but "field" is a clearer and more sensible name (in our opinion).

These are defined for the enum OGRFieldType in GDAL itself.  https://gdal.org/doxygen/ogr__core_8h.html#a787194bea637faf12d61643124a7c9fc

Value

named character vector of the GDAL types for each field

Examples

file <- "list_locality_postcode_meander_valley.tab"
mvfile <- system.file(file.path("extdata/tab", file), package="vapour")
vapour_report_fields(mvfile)

## modified by sql argument
vapour_report_fields(mvfile,
  sql = "SELECT POSTCODE, NAME FROM list_locality_postcode_meander_valley")
vapour_sds_names  

GDAL raster subdatasets (variables)

Description

A subdataset is a collection abstraction for a number of variables within a single GDAL source. If there’s only one variable the datasource and the variable have the same data source string. If there is more than one the subdatasets have the form DRIVER:"datasourcename":varname. Each subdataset name can stand in place of a data source name that has only one variable, so we always treat a source as a subdataset, even if there’s only one.

Usage

vapour_sds_names(x)

Arguments

x  
a data source string, filename, database connection string, Thredds or other URL

Details

Returns a list of datasource and subdataset. In the case of a normal data source, with no subdatasets the value of both entries is the datasource.

Value

list of character vectors, see Details

Examples

f <- system.file("extdata/gdal", "sds.nc", package = "vapour")  
## protect from error with netcdf problems  
result <- try(vapour_sds_names(f), silent = TRUE)  
if (!inherits(result, "try-error")) {  
  print(result)  
}  
vapour_sds_names(system.file("extdata", "sst.tif", package = "vapour"))
vapour_srs_wkt  

PROJ4 string to WKT

**Description**

Convert a projstring to Well Known Text.

**Usage**

vapour_srs_wkt(crs)

**Arguments**

crs  
projection string, see Details.

**Details**

The function is vectorized because why not, but probably only ever will be used on single element vectors of character strings.

Note that no sanitizing is done on inputs, we literally just `OGRSpatialReference.SetFromUserInput(crs)` and give the output as WKT. If it’s an error in GDAL it’s an error in R.

You can get some funky outputs from random strings, so don’t do that. Common sensible inputs are WKT variants, ‘AUTH:CODE’s e.g. ‘EPSG:3031’, the ‘OGC:CRS84’ for long,lat WGS84, ‘ESRI:<code>’ and other authority variants, and datum names such as 'WGS84','NAD27' recognized by PROJ itself.

See help for `SetFromUserInput` in ‘OGRSpatialReference’, and ‘proj_create_crs_to_crs’ in PROJ.

**Value**

WKT2 projection string

**Examples**

vapour_srs_wkt("+proj=laea +datum=WGS84")

---

vapour_vsi_list  

Read GDAL virtual source contents

**Description**

Obtain the names of available items in a virtual file source.

**Usage**

vapour_vsi_list(dsource, ...)

---
vapour_warp_raster

Description

Read a window of data from a GDAL raster source through a warp specification. The warp specification is provided by 'extent', 'dimension', and 'projection' properties of the transformed output.

Arguments

dsource: data source name (path to file, connection string, URL) with virtual prefix, see Details

Details

The dsource must begin with a valid form of the special vsiPREFIX, for details see GDAL Virtual File Systems.

Note that the listing is not recursive, and so cannot be used for automation. One would use this function interactively to determine a useable /vsiPREFIX/dsource data source string.

Value

character vector listing of items

Examples

```r
pointzipfile <- system.file("extdata/vsi/point_shp.zip", package = "vapour", mustWork = TRUE)
vapour_vsi_list(sprintf("/vsizip/%s", pointzipfile))

# Not run:
# example from https://github.com/hypertidy/vapour/issues/55
#url <- "http://dapds00.nci.org.au/thredds/fileServer/rr2/national_geophysical_compilations"
#u <- sprintf("/vsizip/\%s", file.path(url, file))
vapour_vsi_list(u)
# [1] "radmap_v3.2015_filtered_dose" "radmap_v3.2015_filtered_dose.ers"
#gdalinfo /vsitar/home/ubuntu/LT05_L1GS_027026_20060116_20160911_01_T2.tar.gz
#vapour_vsi_list("/vsitar/home/ubuntu/LT05_L1GS_027026_20060116_20160911_01_T2.tar.gz")
#"LT05_L1TP_027026_20061218_20160911_01_T1_ANG.txt"
#"LT05_L1TP_027026_20061218_20160911_01_T1_B1.TIF"
#"LT05_L1TP_027026_20061218_20160911_01_T1_B2.TIF"
#"LT05_L1TP_027026_20061218_20160911_01_T1_B3.TIF"
#...

# End(Not run)
```
vapour_warp_raster

Usage

vapour_warp_raster(  
  x,  
  bands = 1L,  
  extent = NULL,  
  dimension = NULL,  
  projection = "",  
  set_na = TRUE,  
  source_wkt = NULL,  
  source_extent = 0,  
  resample = "near",  
  silent = TRUE,  
  ...,  
  source_geotransform = 0,  
  geotransform = NULL,  
  band_output_type = ",",  
  warp_options = ",",  
  transformation_options = ""  
)

Arguments

x  
vector of data source names (file name or URL or database connection string)

bands  
index of band/s to read (1-based), may be new order or replicated, or NULL (all bands used)

extent  
extent of the target warped raster 'c(xmin, xmax, ymin, ymax)'

dimension  
dimensions in pixels of the warped raster (x, y)

projection  
projection of warped raster (in Well-Known-Text, or any projection string accepted by GDAL)

set_na  
NOT IMPLEMENTED logical, should 'NODATA' values be set to NA

source_wkt  
optional, override or augment the projection of the source (in Well-Known-Text, or any projection string accepted by GDAL)

source_extent  
extent of the source raster, used to override/augment incorrect source metadata

resample  
resampling method used (see details in vapour_read_raster)

silent  
TRUE by default, set to FALSE to report messages

source_geotransform  
DEPRECATED use 'source_extent' (override the native geotransform of the source)

geotransform  
DEPRECATED use 'extent' the affine geotransform of the warped raster

band_output_type  
numeric type of band to apply (else the native type if ") can be one of 'Byte', 'Int32', or 'Float64' but see details in vapour_read_raster()

warp_options  
character vector of options, as in gdalwarp -wo - see Details

transformation_options  
character vector of options, as in gdalwarp -to
Details

Any bands may be read, including repeats.

This function is not memory safe, the source is left on disk but the output raster is all computed in memory so please be careful with very large values for ’dimension’. 1000 * 1000 * 8 for 1000 columns, 1000 rows and floating point double type will be 8Mb.

There’s control over the output type, and is auto-detected from the source (raw/Byte, integer/Int32, numeric/Float64) or can be set with ’band_output_type’.

’projection’ refers to the full Well-Known-Text specification of a coordinate reference system. See vapour_srs_wkt() for conversion from PROJ.4 string to WKT. Any string accepted by GDAL may be used for ’projection’ or ’source_wkt’. including EPSG strings, PROJ4 strings, and file names. Note that this argument was named ’wkt’ up until version 0.8.0.

’extent’ is the four-figure xmin,xmax,ymin,ymax outer corners of corner pixels

’dimension’ is the pixel dimensions of the output, x (ncol) then y (nrow).

Values for missing data are not yet handled, just returned as-is. Note that there may be regions of "zero data" in a warped output, separate from propagated missing "NODATA" values in the source.

Argument ’source_wkt’ may be used to assign the projection of the source, ’source_extent’ to assign the extent of the source. Sometimes both are required.

If multiple sources are specified via ’x’ and either ’source_wkt’ or ’source_extent’ are provided, these are applied to every source even if they have valid values already. If this is not sensible please use VRT to wrap the multiple sources first (see the gdalio package for some in-dev ideas).

Wild combinations of ’source_extent’ and/or ’extent’ may be used for arbitrary flip orientations, scale and offset. For expert usage only. Old versions allowed transform input for target and source but this is now disabled (maybe we’ll write a new wrapper for that).

Value

list of vectors (only 1 for ’band’) of numeric values, in raster order

Options

The ’warp_options’ arguments are for ’warp options -wo’, ’transformation options -to’, ’creation options -co’, ’open options -oo’, or ’dataset open options -doo’, and other arguments that use named options in gdalwarp.

To input use the appropriate argument ’warp_options’ for ’-wo’, ’transformation_options’ for ’-to’.

’warp_options = c("SAMPLE_GRID=YES", "SAMPLE_STEPS=30") ’

Do not include the ’-wo’ or the ’-to’, and make sure each is a separate character element. These are added in turn with ’-wo’ or ’-to’ prepended to the string list in the implementation.

There are no creation options ’-co’ available, because the MEM driver is used. This might changed, see for example ’vapour_write_raster_block’. We might add ’-oo’, ’-doo’ in future.

See GDALWarpOptions for ’-wo’.

See GDAL transformation options for ’-to’.

Note we already apply the following gdalwarp arguments based on input R arguments to this function.
• -of MEM is hardcoded, but may be extended in future  
• -t_srs set via ‘projection’  
• -s_srs set via ‘source_wkt’  
• -te set via ‘extent’  
• -ts set via ‘dimension’  
• -r set via ‘resample’  

Note that ‘source_extent’ does nothing atm, there’s no -se (you have to use VRT and we’ll do that via new /vsivrt/ ...) bundle any required options into ‘options’.

Examples

```r
b <- 4e5
f <- system.file("extdata", "sst.tif", package = "vapour")
prj <- "+proj=aeqd +lon_0=147 +lat_0=-42"
vals <- vapour_warp_raster(f, extent = c(-b, b, -b, b),
dimension = c(186, 298),
bands = 1,
projection = vapour_srs_wkt(prj),
warp_options = c("SAMPLE_GRID=YES"))

image(list(x = seq(-b, b, length.out = 187), y = seq(-b, b, length.out = 298),
z = matrix(unlist(vals, use.names = FALSE), 186)[,298:1]), asp = 1)
```

vapour_warp_raster_raw

type safe(r) raster warp

Description

These wrappers around `vapour_warp_raster()` guarantee single vector output of the nominated type.

Usage

```r
vapour_warp_raster_raw(
  x,
  bands = 1L,
  extent = NULL,
  dimension = NULL,
  projection = "",
```

vapour_warp_raster_raw

set_na = TRUE,

)

Arguments

x
bands
extent
dimension
projection
set_na
source_wkt
source_extent
resample
silent
...
warp_options
transformation_options

vector of data source names (file name or URL or database connection string)

index of band/s to read (1-based), may be new order or replicated, or NULL (all bands used)
extent of the target warped raster 'c(xmin, xmax, ymin, ymax)'
dimensions in pixels of the warped raster (x, y)
projection of warped raster (in Well-Known-Text, or any projection string accepted by GDAL)

NOT IMPLEMENTED logical, should 'NODATA' values be set to NA

optional, override or augment the projection of the source (in Well-Known-Text, or any projection string accepted by GDAL)
extent of the source raster, used to override/augment incorrect source metadata
resampling method used (see details in vapour_read_raster)
TRUE by default, set to FALSE to report messages

character vector of options, as in gdalwarp -wo - see Details
character vector of options, as in gdalwarp -to
Details

_hex and _chr are aliases of each other.

Value

atomic vector of the nominated type raw, int, dbl, or character (hex)

Examples

```r
b <- 4e5
f <- system.file("extdata", "sst.tif", package = "vapour")
prj <- "+proj=aeqd +lon_0=147 +lat_0=-42"
bytes <- vapour_warp_raster_raw(f, extent = c(-b, b, -b, b),
                               dimension = c(18, 2),
                               bands = 1,
                               projection = prj)
# not useful given source type floating point, but works
str(bytes)
```
