Package ‘varImp’

May 23, 2020

Title RF Variable Importance for Arbitrary Measures

Version 0.4

Description Computes the random forest variable importance (VIMP) for the conditional inference random forest (cforest) of the 'party' package. Includes a function (varImp) that computes the VIMP for arbitrary measures from the 'measures' package. For calculating the VIMP regarding the measures accuracy and AUC two extra functions exist (varImpACC and varImpAUC).

Index 7
Description

Computes the variable importance for arbitrary measures from the 'measures' package.

Usage

```r
varImp(
  object,
  mincriterion = 0,
  conditional = FALSE,
  threshold = 0.2,
  nperm = 1,
  OOB = TRUE,
  pre1.0_0 = conditional,
  measure = "multiclass.Brier",
  ...
)
```

Arguments

- **object**: An object as returned by `cforest`.
- **mincriterion**: The value of the test statistic or 1 - p-value that must be exceeded in order to include a split in the computation of the importance. The default `mincriterion = 0` guarantees that all splits are included.
- **conditional**: A logical determining whether unconditional or conditional computation of the importance is performed.
- **threshold**: The threshold value for (1 - p-value) of the association between the variable of interest and a covariate, which must be exceeded in order to include the covariate in the conditioning scheme for the variable of interest (only relevant if `conditional = TRUE`). A threshold value of zero includes all covariates.
- **nperm**: The number of permutations performed.
- **OOB**: A logical determining whether the importance is computed from the out-of-bag sample or the learning sample (not suggested).
- **pre1.0_0**: Prior to party version 1.0-0, the actual data values were permuted according to the original permutation importance suggested by Breiman (2001). Now the assignments to child nodes of splits in the variable of interest are permuted as described by Hapfelmeier et al. (2012), which allows for missing values in the explanatory variables and is more efficient wrt memory consumption and computing time. This method does not apply to conditional variable importances.
- **measure**: The name of the measure of the 'measures' package that should be used for the variable importance calculation.
- **...**: Further arguments (like positive or negative class) that are needed by the measure.
Details

Many measures have not been tested for the usefulness of random forests variable importance. Use at your own risk.

Value

Vector with computed permutation importance for each variable.

Examples

```r
# multiclass case
data(iris)
iris.cf = cforest(Species ~ ., data = iris, control = cforest_unbiased(mtry = 2, ntree = 50))
set.seed(123)
vimp = varImp(object = iris.cf, measure = "multiclass.Brier")
vimp
```

Description

Computes the variable importance regarding the accuracy (ACC).

Usage

```r
varImpACC(
  object,
  mincriterion = 0,
  conditional = FALSE,
  threshold = 0.2,
  nperm = 1,
  OOB = TRUE,
  pre1.0_0 = conditional
)
```

Arguments

- **object**: An object as returned by `cforest`.
- **mincriterion**: The value of the test statistic or 1 - p-value that must be exceeded in order to include a split in the computation of the importance. The default `mincriterion` = 0 guarantees that all splits are included.
- **conditional**: The value of the test statistic or 1 - p-value that must be exceeded in order to include a split in the computation of the importance. The default `conditional` = 0 guarantees that all splits are included.
threshold

The threshold value for \((1 - p\text{-value})\) of the association between the variable of interest and a covariate, which must be exceeded inorder to include the covariate in the conditioning scheme for the variable of interest (only relevant if conditional = TRUE). A threshold value of zero includes all covariates.

nperm

The number of permutations performed.

OOB

A logical determining whether the importance is computed from the out-of-bag sample or the learning sample (not suggested).

pre1.0_0

Prior to party version 1.0-0, the actual data values were permuted according to the original permutation importance suggested by Breiman (2001). Now the assignments to child nodes of splits in the variable of interest are permuted as described by Hapfelmeier et al. (2012), which allows for missing values in the explanatory variables and is more efficient wrt memory consumption and computing time. This method does not apply to conditional variable importances.

Value

Vector with computed permutation importance for each variable

Examples

data(iris)
iris2 = iris
iris2$Species = factor(iris$Species == "versicolor")
iris.cf = cforest(Species ~ ., data = iris2,control = cforest_unbiased(mtry = 2, ntree = 50))
set.seed(123)
a = varImpACC(object = iris.cf)
Arguments

object An object as returned by cforest.

mincriterion The value of the test statistic or 1 - p-value that must be exceeded in order to include a split in the computation of the importance. The default mincriterion = 0 guarantees that all splits are included.

conditional The value of the test statistic or 1 - p-value that must be exceeded in order to include a split in the computation of the importance. The default mincriterion = 0 guarantees that all splits are included.

threshold The threshold value for (1 - p-value) of the association between the variable of interest and a covariate, which must be exceeded inorder to include the covariate in the conditioning scheme for the variable of interest (only relevant if conditional = TRUE). A threshold value of zero includes all covariates.

nperm The number of permutations performed.

OOB A logical determining whether the importance is computed from the out-of-bag sample or the learning sample (not suggested).

pre1.0_0 Prior to party version 1.0-0, the actual data values were permuted according to the original permutation importance suggested by Breiman (2001). Now the assignments to child nodes of splits in the variable of interest are permuted as described by Hapfelmeier et al. (2012), which allows for missing values in the explanatory variables and is more efficient wrt memory consumption and computing time. This method does not apply to conditional variable importances.

Details

For using the original AUC definition and multiclass AUC you can use the varImp function and specify the particular measure.

Value

Vector with computed permutation importance for each variable

Examples

# multiclass case
data(iris)
iris2 = iris
iris2$Species = factor(iris$Species == "versicolor")
iris.cf = cforest(Species ~ ., data = iris2,control = cforest_unbiased(mtry = 2, ntree = 50))
set.seed(123)
varImpAUC(object = iris.cf)
varImpRanger

Description

Computes the variable importance for ranger models and for arbitrary measures from the 'measures' package.

Usage

varImpRanger(object, data, target, nperm = 1, measure = "multiclass.Brier")

Arguments

- object: An object as returned by cforest. ranger with option keep.inbag = TRUE.
- data: Original data that was used for training the random forest.
- target: Target variable as used in the trained model.
- nperm: The number of permutations performed.
- measure: The name of the measure of the 'measures' package that should be used for the variable importance calculation.

Value

Vector with computed permutation importance for each variable.

Examples

```r
## Not run:
library(ranger)
iris.rg = ranger(Species ~ ., data = iris, keep.inbag = TRUE, probability = TRUE)
vimp.ranger = varImpRanger(object = iris.rg, data = iris, target = "Species")
vimp.ranger

## End(Not run)
