

Package ‘vroom’

May 14, 2019

Title Read and Write Rectangular Text Data Quickly

Version 1.0.1

Description The goal of 'vroom' is to read and write data (like 'csv', 'tsv' and 'fwf') quickly. When reading it uses a quick initial indexing step, then reads the values lazily, so only the data you actually use needs to be read. The writer formats the data in parallel and writes to disk asynchronously from formatting.

cols	<i>Create column specification</i>
------	------------------------------------

Description

cols() includes all columns in the input data, guessing the column types as the default. cols_only() includes only the columns you explicitly specify, skipping the rest.

Usage

```
cols(..., .default = col_guess())
```

```
cols_only(...)
```

```
col_logical(...)
```

```
col_integer(...)
```

```
col_double(...)
```

```

col_character(...)
col_skip(...)
col_number(...)
col_guess(...)
col_factor(levels = NULL, ordered = FALSE, include_na = FALSE, ...)
col_datetime(format = "", ...)
col_date(format = "", ...)
col_time(format = "", ...)

```

Arguments

...	Either column objects created by <code>col_*</code> (), or their abbreviated character names (as described in the <code>col_types</code> argument of <code>vroom()</code>). If you're only overriding a few columns, it's best to refer to columns by name. If not named, the column types must match the column names exactly. In <code>col_*</code> () functions these are stored in the object.
.default	Any named columns not explicitly overridden in ... will be read with this column type.
levels	Character vector providing set of allowed levels. if NULL, will generate levels based on the unique values of x, ordered by order of appearance in x.
ordered	Is it an ordered factor?
include_na	If NA are present, include as an explicit factor to level?
format	A format specification, as described below. If set to "", date times are parsed as ISO8601, dates and times used the date and time formats specified in the <code>locale()</code> . Unlike <code>strptime()</code> , the format specification must match the complete string.

Details

The available specifications are: (with string abbreviations in brackets)

- `col_logical()` [l], containing only T, F, TRUE or FALSE.
- `col_integer()` [i], integers.
- `col_double()` [d], doubles.
- `col_character()` [c], everything else.
- `col_factor(levels, ordered)` [f], a fixed set of values.
- `col_date(format = "")` [D]: with the locale's `date_format`.
- `col_time(format = "")` [t]: with the locale's `time_format`.

Value

A col_spec object.

Examples

```
df <- vroom(vroom_example("mtcars.csv"))
s <- spec(df)
s

cols_condense(s)
```

date_names

Create or retrieve date names

Description

When parsing dates, you often need to know how weekdays of the week and months are represented as text. This pair of functions allows you to either create your own, or retrieve from a standard list. The standard list is derived from ICU (<http://site.icu-project.org>) via the *stringi* package.

Usage

```
date_names(mon, mon_ab = mon, day, day_ab = day, am_pm = c("AM",
  "PM"))

date_names_lang(language)

date_names_langs()
```

Arguments

mon, mon_ab	Full and abbreviated month names.
day, day_ab	Full and abbreviated week day names. Starts with Sunday.
am_pm	Names used for AM and PM.
language	A BCP 47 locale, made up of a language and a region, e.g. "en_US" for American English. See <code>date_names_langs()</code> for a complete list of available locales.

Examples

```
date_names_lang("en")
date_names_lang("ko")
date_names_lang("fr")
```

 generators

Generate individual vectors of the types supported by vroom

Description

Generate individual vectors of the types supported by vroom

Usage

```
gen_character(n, min = 5, max = 25, values = c(letters, LETTERS,
  0:9), ...)
```

```
gen_double(n, f = stats::rnorm, ...)
```

```
gen_number(n, f = stats::rnorm, ...)
```

```
gen_integer(n, min = 1L, max = .Machine$integer.max, prob = NULL,
  ...)
```

```
gen_factor(n, levels = NULL, ordered = FALSE,
  num_levels = gen_integer(1L, 1L, 25L), ...)
```

```
gen_time(n, min = 0, max = hms::hms(days = 1), fractional = FALSE,
  ...)
```

```
gen_date(n, min = as.Date("2001-01-01"), max = as.Date("2021-01-01"),
  ...)
```

```
gen_datetime(n, min = as.POSIXct("2001-01-01"),
  max = as.POSIXct("2021-01-01"), tz = "UTC", ...)
```

```
gen_logical(n, ...)
```

```
gen_name(n)
```

Arguments

n	The size of the vector to generate
min	The minimum range for the vector
max	The maximum range for the vector
values	The explicit values to use.
...	Additional arguments passed to internal generation functions
f	The random function to use.
prob	a vector of probability weights for obtaining the elements of the vector being sampled.

levels	The explicit levels to use, if NULL random levels are generated using <code>gen_name()</code> .
ordered	Should the factors be ordered factors?
num_levels	The number of factor levels to generate
fractional	Whether to generate times with fractional seconds
tz	The timezone to use for dates

Examples

```
# characters
gen_character(4)

# factors
gen_factor(4)

# logical
gen_logical(4)

# numbers
gen_double(4)
gen_integer(4)

# temporal data
gen_time(4)
gen_date(4)
gen_datetime(4)
```

gen_tbl	<i>Generate a random tibble</i>
---------	---------------------------------

Description

This is useful for benchmarking, but also for bug reports when you cannot share the real dataset.

Usage

```
gen_tbl(rows, cols = NULL, col_types = NULL,
        locale = default_locale(), missing = 0)
```

Arguments

rows	Number of rows to generate
cols	Number of columns to generate, if NULL this is derived from <code>col_types</code> .
col_types	One of NULL, a <code>cols()</code> specification, or a string. See <code>vignette("readr")</code> for more details. If NULL, all column types will be imputed from the first 1000 rows on the input. This is convenient (and fast), but not robust. If the imputation fails, you'll need to supply the correct types yourself.

If a column specification created by `cols()`, it must contain one column specification for each column. If you only want to read a subset of the columns, use `cols_only()`.

Alternatively, you can use a compact string representation where each character represents one column: c = character, i = integer, n = number, d = double, l = logical, f = factor, D = date, T = date time, t = time, ? = guess, or `_/-` to skip the column.

locale	The locale controls defaults that vary from place to place. The default locale is US-centric (like R), but you can use <code>locale()</code> to create your own locale that controls things like the default time zone, encoding, decimal mark, big mark, and day/month names.
missing	The percentage (from 0 to 1) of missing data to use

Details

There is also a family of functions to generate individual vectors of each type.

See Also

[generators](#) to generate individual vectors.

Examples

```
# random 10 x 5 table with random column types
rand_tbl <- gen_tbl(10, 5)
rand_tbl

# all double 25 x 4 table
dbl_tbl <- gen_tbl(25, 4, col_types = "dddd")
dbl_tbl

# Use the dots in long form column types to change the random function and options
types <- rep(times = 4, list(col_double(f = stats::runif, min = -10, max = 25)))
types
dbl_tbl2 <- gen_tbl(25, 4, col_types = types)
dbl_tbl2
```

guess_type

Guess the type of a vector

Description

Guess the type of a vector

Usage

```
guess_type(x, na = c("", "NA"), locale = default_locale(),
  guess_integer = FALSE)
```

Arguments

x	Character vector of values to parse.
na	Character vector of strings to interpret as missing values. Set this option to <code>character()</code> to indicate no missing values.
locale	The locale controls defaults that vary from place to place. The default locale is US-centric (like R), but you can use <code>locale()</code> to create your own locale that controls things like the default time zone, encoding, decimal mark, big mark, and day/month names.
guess_integer	If TRUE, guess integer types for whole numbers, if FALSE guess numeric type for all numbers.

Examples

```
# Logical vectors
guess_type(c("FALSE", "TRUE", "F", "T"))
# Integers and doubles
guess_type(c("1", "2", "3"))
guess_type(c("1.6", "2.6", "3.4"))
# Numbers containing grouping mark
guess_type("1,234,566")
# ISO 8601 date times
guess_type(c("2010-10-10"))
guess_type(c("2010-10-10 01:02:03"))
guess_type(c("01:02:03 AM"))
```

 locale

Create locales

Description

A locale object tries to capture all the defaults that can vary between countries. You set the locale in once, and the details are automatically passed on down to the columns parsers. The defaults have been chosen to match R (i.e. US English) as closely as possible. See `vignette("locales")` for more details.

Usage

```
locale(date_names = "en", date_format = "%AD", time_format = "%AT",
       decimal_mark = ".", grouping_mark = ",", tz = "UTC",
       encoding = "UTF-8")
```

```
default_locale()
```

Arguments

<code>date_names</code>	Character representations of day and month names. Either the language code as string (passed on to <code>date_names_lang()</code>) or an object created by <code>date_names()</code> .
<code>date_format</code> , <code>time_format</code>	Default date and time formats.
<code>decimal_mark</code> , <code>grouping_mark</code>	Symbols used to indicate the decimal place, and to chunk larger numbers. Decimal mark can only be <code>,</code> or <code>.</code>
<code>tz</code>	Default tz. This is used both for input (if the time zone isn't present in individual strings), and for output (to control the default display). The default is to use "UTC", a time zone that does not use daylight savings time (DST) and hence is typically most useful for data. The absence of time zones makes it approximately 50x faster to generate UTC times than any other time zone. Use "" to use the system default time zone, but beware that this will not be reproducible across systems. For a complete list of possible time zones, see <code>OlsonNames()</code> . Americans, note that "EST" is a Canadian time zone that does not have DST. It is <i>not</i> Eastern Standard Time. It's better to use "US/Eastern", "US/Central" etc.
<code>encoding</code>	Default encoding.

Examples

```
locale()
locale("fr")

# South American locale
locale("es", decimal_mark = ",")
```

vroom	<i>Read a delimited file into a tibble</i>
-------	--

Description

Read a delimited file into a tibble

Usage

```
vroom(file, delim = NULL, col_names = TRUE, col_types = NULL,
      col_select = NULL, id = NULL, skip = 0, n_max = Inf, na = c("",
      "NA"), quote = "\"", comment = "", trim_ws = TRUE,
      escape_double = TRUE, escape_backslash = FALSE,
      locale = default_locale(), guess_max = 100, altrep_opts = "chr",
      num_threads = vroom_threads(), progress = vroom_progress(),
      .name_repair = "unique")
```

Arguments

file	path to a local file.
delim	One or more characters used to delimit fields within a record. If NULL the delimiter is guessed from the set of c(", ", "\t", " ", " ", ":", ";", "\n").
col_names	<p>Either TRUE, FALSE or a character vector of column names.</p> <p>If TRUE, the first row of the input will be used as the column names, and will not be included in the data frame. If FALSE, column names will be generated automatically: X1, X2, X3 etc.</p> <p>If col_names is a character vector, the values will be used as the names of the columns, and the first row of the input will be read into the first row of the output data frame.</p> <p>Missing (NA) column names will generate a warning, and be filled in with dummy names X1, X2 etc. Duplicate column names will generate a warning and be made unique with a numeric prefix.</p>
col_types	<p>One of NULL, a <code>cols()</code> specification, or a string. See <code>vignette("readr")</code> for more details.</p> <p>If NULL, all column types will be imputed from the first 1000 rows on the input. This is convenient (and fast), but not robust. If the imputation fails, you'll need to supply the correct types yourself.</p> <p>If a column specification created by <code>cols()</code>, it must contain one column specification for each column. If you only want to read a subset of the columns, use <code>cols_only()</code>.</p> <p>Alternatively, you can use a compact string representation where each character represents one column: c = character, i = integer, n = number, d = double, l = logical, f = factor, D = date, T = date time, t = time, ? = guess, or <code>_/-</code> to skip the column.</p>
col_select	One or more selection expressions, like in <code>dplyr::select()</code> . Use <code>c()</code> or <code>list()</code> to use more than one expression. See <code>?dplyr::select</code> for details on available selection options.
id	Either a string or 'NULL'. If a string, the output will contain a variable with that name with the filename(s) as the value. If 'NULL', the default, no variable will be created.
skip	Number of lines to skip before reading data.
n_max	Maximum number of records to read.
na	Character vector of strings to interpret as missing values. Set this option to <code>character()</code> to indicate no missing values.
quote	Single character used to quote strings.
comment	A string used to identify comments. Any text after the comment characters will be silently ignored.
trim_ws	Should leading and trailing whitespace be trimmed from each field before parsing it?
escape_double	Does the file escape quotes by doubling them? i.e. If this option is TRUE, the value <code>""</code> represents a single quote, <code>'</code> .

<code>escape_backslash</code>	Does the file use backslashes to escape special characters? This is more general than <code>escape_double</code> as backslashes can be used to escape the delimiter character, the quote character, or to add special characters like <code>\n</code> .
<code>locale</code>	The locale controls defaults that vary from place to place. The default locale is US-centric (like R), but you can use <code>locale()</code> to create your own locale that controls things like the default time zone, encoding, decimal mark, big mark, and day/month names.
<code>guess_max</code>	Maximum number of records to use for guessing column types.
<code>altrep_opts</code>	Control which column types use Altrep representations, either a character vector of types, TRUE or FALSE. See <code>vroom_altrep_opts()</code> for full details.
<code>num_threads</code>	Number of threads to use when reading and materializing vectors.
<code>progress</code>	Display a progress bar? By default it will only display in an interactive session and not while knitting a document. The display is updated every 50,000 values and will only display if estimated reading time is 5 seconds or more. The automatic progress bar can be disabled by setting option <code>readr.show_progress</code> to FALSE.
<code>.name_repair</code>	Handling of column names. By default, vroom ensures column names are not empty and unique. See <code>.name_repair</code> as documented in <code>tibble::tibble()</code> for additional options including supplying user defined name repair functions.

Examples

```
# Input sources -----
# Read from a path
vroom("mtcars.tsv")
vroom("mtcars.tsv.gz")
vroom("mtcars.tsv.bz2")

## Not run:
# Including remote paths
vroom("https://github.com/r-lib/vroom/raw/master/inst/extdata/mtcars.csv")

## End(Not run)

# Or directly from a string (must contain a trailing newline)
vroom("x,y\n1,2\n3,4\n")

# Column selection -----
# Pass column names or indexes directly to select them
vroom("mtcars.tsv", col_select = c(model, cyl, gear))
vroom("mtcars.tsv", col_select = c(1, 3, 11))

# Or use the selection helpers
vroom("mtcars.tsv", col_select = starts_with("d"))

# You can also rename specific columns
```

```

vroom("mtcars.tsv", col_select = list(car = model, everything()))

# Column types -----
# By default, vroom guesses the columns types, looking at 1000 rows
# throughout the dataset.
# You can specify them explicitly with a compact specification:
vroom("x,y\n1,2\n3,4\n", col_types = "dc")

# Or with a list of column types:
vroom("x,y\n1,2\n3,4\n", col_types = list(col_double(), col_character()))

# File types -----
# csv
vroom("a,b\n1.0,2.0\n", delim = ",")
# tsv
vroom("a\tb\n1.0\t2.0\n")
# Other delimiters
vroom("a|b\n1.0|2.0\n", delim = "|")

```

vroom_altrep_opts *Show which column types are using Altrep*

Description

vroom_altrep_opts() can be used directly as input to the altrep_opts argument of [vroom\(\)](#).

Usage

```
vroom_altrep_opts(which = NULL)
```

Arguments

which A character vector of column types to use Altrep for. Can also take TRUE or FALSE to use Altrep for all possible or none of the types

Details

Alternatively there is also a family of environment variables to control use of the Altrep framework. These can then be set in your .Renviron file, e.g. with [usethis::edit_r_environ\(\)](#). For versions of R where the Altrep framework is unavailable (R < 3.5.0) they are automatically turned off and the variables have no effect. The variables can take one of true, false, TRUE, FALSE, 1, or 0.

- VROOM_USE_ALTREP_NUMERICS - If set use Altrep for *all* numeric types (default false).

There are also individual variables for each type. Currently only VROOM_USE_ALTREP_CHR defaults to true.

- VROOM_USE_ALTREP_CHR
- VROOM_USE_ALTREP_FCT

- VROOM_USE_ALTREP_INT
- VROOM_USE_ALTREP_DBL
- VROOM_USE_ALTREP_NUM
- VROOM_USE_ALTREP_LGL
- VROOM_USE_ALTREP_DTTM
- VROOM_USE_ALTREP_DATE
- VROOM_USE_ALTREP_TIME

Examples

```
vroom_altrep_opts()
vroom_altrep_opts(c("chr", "fct", "int"))
vroom_altrep_opts(TRUE)
vroom_altrep_opts(FALSE)
```

vroom_example	<i>Get path to vroom examples</i>
---------------	-----------------------------------

Description

vroom comes bundled with a number of sample files in its 'inst/extdata' directory. Use `vroom_examples()` to list all the available examples and `vroom_example()` to retrieve the path to one example.

Usage

```
vroom_example(path)

vroom_examples(pattern = NULL)
```

Arguments

path	Name of file.
pattern	A regular expression of filenames to match. If NULL all available files are returned. listed.

Examples

```
# List all available examples
vroom_examples()

# Get path to one example
vroom_example("mtcars.csv")
```

vroom_format	<i>Convert a data frame to a delimited string</i>
--------------	---

Description

This is equivalent to `vroom_write()`, but instead of writing to disk, it returns a string. It is primarily useful for examples and for testing.

Usage

```
vroom_format(x, delim = "\t", na = "NA", col_names = TRUE,
  escape = c("double", "backslash", "none"), quote = c("needed", "all",
  "none"), bom = FALSE)
```

Arguments

x	A data frame to write to disk
delim	One or more characters used to delimit fields within a record. If NULL the delimiter is guessed from the set of <code>c(", ", "\t", " ", " ", ":", ";", "\n")</code> .
na	Character vector of strings to interpret as missing values. Set this option to <code>character()</code> to indicate no missing values.
col_names	Either TRUE, FALSE or a character vector of column names. If TRUE, the first row of the input will be used as the column names, and will not be included in the data frame. If FALSE, column names will be generated automatically: X1, X2, X3 etc. If col_names is a character vector, the values will be used as the names of the columns, and the first row of the input will be read into the first row of the output data frame. Missing (NA) column names will generate a warning, and be filled in with dummy names X1, X2 etc. Duplicate column names will generate a warning and be made unique with a numeric prefix.
escape	The type of escape to use when quotes are in the data. <ul style="list-style-type: none"> • double - quotes are escaped by doubling them. • backslash - quotes are escaped by a preceding backslash. • none - quotes are not escaped.
quote	How to handle fields which contain characters that need to be quoted. <ul style="list-style-type: none"> • needed - Only quote fields which need them. • all - Quote all fields. • none - Never quote fields.
bom	If TRUE add a UTF-8 BOM at the beginning of the file. This is recommended when saving data for consumption by excel, as it will force excel to read the data with the correct encoding (UTF-8)

vroom_fwf

*Read a fixed width file into a tibble***Description**

Read a fixed width file into a tibble

Usage

```
vroom_fwf(file, col_positions = fwf_empty(file[[1]], skip, n =
  guess_max), col_types = NULL, col_select = NULL, id = NULL,
  locale = default_locale(), na = c("", "NA"), comment = "",
  trim_ws = TRUE, skip = 0, n_max = Inf, guess_max = 100,
  num_threads = vroom_threads(), progress = vroom_progress(),
  .name_repair = "unique")

fwf_empty(file, skip = 0, col_names = NULL, comment = "", n = 100L)

fwf_widths(widths, col_names = NULL)

fwf_positions(start, end = NULL, col_names = NULL)

fwf_cols(...)
```

Arguments

file	<p>Either a path to a file, a connection, or literal data (either a single string or a raw vector).</p> <p>Files ending in .gz, .bz2, .xz, or .zip will be automatically uncompressed. Files starting with http://, https://, ftp://, or ftps:// will be automatically downloaded. Remote gz files can also be automatically downloaded and decompressed.</p> <p>Literal data is most useful for examples and tests. It must contain at least one new line to be recognised as data (instead of a path) or be a vector of greater than length 1.</p> <p>Using a value of <code>clipboard()</code> will read from the system clipboard.</p>
col_positions	<p>Column positions, as created by <code>fwf_empty()</code>, <code>fwf_widths()</code> or <code>fwf_positions()</code>. To read in only selected fields, use <code>fwf_positions()</code>. If the width of the last column is variable (a ragged fwf file), supply the last end position as NA.</p>
col_types	<p>One of NULL, a <code>cols()</code> specification, or a string. See <code>vignette("readr")</code> for more details.</p> <p>If NULL, all column types will be imputed from the first 1000 rows on the input. This is convenient (and fast), but not robust. If the imputation fails, you'll need to supply the correct types yourself.</p>

If a column specification created by `cols()`, it must contain one column specification for each column. If you only want to read a subset of the columns, use `cols_only()`.

Alternatively, you can use a compact string representation where each character represents one column: `c` = character, `i` = integer, `n` = number, `d` = double, `l` = logical, `f` = factor, `D` = date, `T` = date time, `t` = time, `?` = guess, or `_/-` to skip the column.

<code>col_select</code>	One or more selection expressions, like in <code>dplyr::select()</code> . Use <code>c()</code> or <code>list()</code> to use more than one expression. See <code>?dplyr::select</code> for details on available selection options.
<code>id</code>	Either a string or <code>'NULL'</code> . If a string, the output will contain a variable with that name with the filename(s) as the value. If <code>'NULL'</code> , the default, no variable will be created.
<code>locale</code>	The locale controls defaults that vary from place to place. The default locale is US-centric (like R), but you can use <code>locale()</code> to create your own locale that controls things like the default time zone, encoding, decimal mark, big mark, and day/month names.
<code>na</code>	Character vector of strings to interpret as missing values. Set this option to <code>character()</code> to indicate no missing values.
<code>comment</code>	A string used to identify comments. Any text after the comment characters will be silently ignored.
<code>trim_ws</code>	Should leading and trailing whitespace be trimmed from each field before parsing it?
<code>skip</code>	Number of lines to skip before reading data.
<code>n_max</code>	Maximum number of records to read.
<code>guess_max</code>	Maximum number of records to use for guessing column types.
<code>num_threads</code>	Number of threads to use when reading and materializing vectors.
<code>progress</code>	Display a progress bar? By default it will only display in an interactive session and not while knitting a document. The display is updated every 50,000 values and will only display if estimated reading time is 5 seconds or more. The automatic progress bar can be disabled by setting option <code>readr.show_progress</code> to <code>FALSE</code> .
<code>.name_repair</code>	Handling of column names. By default, vroom ensures column names are not empty and unique. See <code>.name_repair</code> as documented in <code>tibble::tibble()</code> for additional options including supplying user defined name repair functions.
<code>col_names</code>	Either <code>NULL</code> , or a character vector column names.
<code>n</code>	Number of lines the tokenizer will read to determine file structure. By default it is set to 100.
<code>widths</code>	Width of each field. Use <code>NA</code> as width of last field when reading a ragged fwf file.
<code>start, end</code>	Starting and ending (inclusive) positions of each field. Use <code>NA</code> as last end field when reading a ragged fwf file.

... If the first element is a data frame, then it must have all numeric columns and either one or two rows. The column names are the variable names. The column values are the variable widths if a length one vector, and if length two, variable start and end positions. The elements of ... are used to construct a data frame with or or two rows as above.

Examples

```
fwf_sample <- vroom_example("fwf-sample.txt")
cat(readLines(fwf_sample))

# You can specify column positions in several ways:
# 1. Guess based on position of empty columns
vroom_fwf(fwf_sample, fwf_empty(fwf_sample, col_names = c("first", "last", "state", "ssn")))
# 2. A vector of field widths
vroom_fwf(fwf_sample, fwf_widths(c(20, 10, 12), c("name", "state", "ssn")))
# 3. Paired vectors of start and end positions
vroom_fwf(fwf_sample, fwf_positions(c(1, 30), c(20, 42), c("name", "ssn")))
# 4. Named arguments with start and end positions
vroom_fwf(fwf_sample, fwf_cols(name = c(1, 20), ssn = c(30, 42)))
# 5. Named arguments with column widths
vroom_fwf(fwf_sample, fwf_cols(name = 20, state = 10, ssn = 12))
```

vroom_lines

Read lines from a file

Description

vroom_lines() is similar to readLines(), however it reads the lines lazily like vroom(), so operations like length(), head(), tail() and sample() can be done much more efficiently without reading all the data into R.

Usage

```
vroom_lines(file, n_max = Inf, skip = 0, altrep_opts = "chr",
  num_threads = vroom_threads(), progress = vroom_progress())
```

Arguments

file	path to a local file.
n_max	Maximum number of records to read.
skip	Number of lines to skip before reading data.
altrep_opts	Control which column types use Altrep representations, either a character vector of types, TRUE or FALSE. See vroom_altrep_opts() for full details.
num_threads	Number of threads to use when reading and materializing vectors.

`progress` Display a progress bar? By default it will only display in an interactive session and not while knitting a document. The display is updated every 50,000 values and will only display if estimated reading time is 5 seconds or more. The automatic progress bar can be disabled by setting option `readr.show_progress` to `FALSE`.

Examples

```
lines <- vroom_lines(vroom_example("mtcars.csv"))

length(lines)
head(lines, n = 2)
tail(lines, n = 2)
sample(lines, size = 2)
```

<code>vroom_progress</code>	<i>Determine if progress bars should be shown</i>
-----------------------------	---

Description

Progress bars are shown *unless* one of the following is TRUE

- The bar is explicitly disabled by setting `Sys.getenv("VROOM_SHOW_PROGRESS"="false")`
- The code is run in a non-interactive session (`interactive()` is `FALSE`).
- The code is run in an RStudio notebook chunk.
- The code is run by `knitr / rmarkdown`.
- The code is run by `testthat` (the `TESTTHAT` envvar is `true`).

Usage

```
vroom_progress()
```

Examples

```
vroom_progress()
```

vroom_str	<i>Structure of objects</i>
-----------	-----------------------------

Description

Similar to `str()` but with more information for Altrep objects.

Usage

```
vroom_str(x)
```

Arguments

x	a vector
---	----------

Examples

```
# when used on non-altrep objects altrep will always be false
vroom_str(mtcars)

mt <- vroom(vroom_example("mtcars.csv"), ",", altrep_opts = c("chr", "dbl"))
vroom_str(mt)
```

vroom_write	<i>Write a data frame to a delimited file</i>
-------------	---

Description

Write a data frame to a delimited file

Usage

```
vroom_write(x, path, delim = "\t", na = "NA", col_names = !append,
  append = FALSE, quote = c("needed", "all", "none"),
  escape = c("double", "backslash", "none"), bom = FALSE,
  num_threads = vroom_threads(), progress = vroom_progress())
```

Arguments

x	A data frame to write to disk
path	Path or connection to write to.
delim	One of more characters used to delimiter fields within a record. If NULL the delimiter is guessed from the set of <code>c(", ", "\t", " ", " ", ":", ";", "\n")</code> .
na	Character vector of strings to interpret as missing values. Set this option to <code>character()</code> to indicate no missing values.

col_names	<p>Either TRUE, FALSE or a character vector of column names.</p> <p>If TRUE, the first row of the input will be used as the column names, and will not be included in the data frame. If FALSE, column names will be generated automatically: X1, X2, X3 etc.</p> <p>If col_names is a character vector, the values will be used as the names of the columns, and the first row of the input will be read into the first row of the output data frame.</p> <p>Missing (NA) column names will generate a warning, and be filled in with dummy names X1, X2 etc. Duplicate column names will generate a warning and be made unique with a numeric prefix.</p>
append	<p>If FALSE, will overwrite existing file. If TRUE, will append to existing file. In both cases, if file does not exist a new file is created.</p>
quote	<p>How to handle fields which contain characters that need to be quoted.</p> <ul style="list-style-type: none"> • needed - Only quote fields which need them. • all - Quote all fields. • none - Never quote fields.
escape	<p>The type of escape to use when quotes are in the data.</p> <ul style="list-style-type: none"> • double - quotes are escaped by doubling them. • backslash - quotes are escaped by a preceding backslash. • none - quotes are not escaped.
bom	<p>If TRUE add a UTF-8 BOM at the beginning of the file. This is recommended when saving data for consumption by excel, as it will force excel to read the data with the correct encoding (UTF-8)</p>
num_threads	<p>Number of threads to use when reading and materializing vectors.</p>
progress	<p>Display a progress bar? By default it will only display in an interactive session and not while knitting a document. The display is updated every 50,000 values and will only display if estimated reading time is 5 seconds or more. The automatic progress bar can be disabled by setting option readr.show_progress to FALSE.</p>

Examples

```
# If you only specify a file name, vroom_write() will write
# the file to your current working directory.
vroom_write(mtcars, "mtcars.tsv")
vroom_write(mtcars, "mtcars.csv", ",")

# If you add an extension to the file name, write_* will
# automatically compress the output.
vroom_write(mtcars, "mtcars.tsv.gz")
vroom_write(mtcars, "mtcars.tsv.bz2")
vroom_write(mtcars, "mtcars.tsv.xz")
```
