Package ‘yardstick’

November 22, 2021

Type Package

Title Tidy Characterizations of Model Performance

Version 0.0.9

Description Tidy tools for quantifying how well model fits to a data set such as confusion matrices, class probability curve summaries, and regression metrics (e.g., RMSE).

accuracy

Description
Accuracy is the proportion of the data that are predicted correctly.

Usage
accuracy(data, ...)

## S3 method for class 'data.frame'
accuracy(data, truth, estimate, na_rm = TRUE, ...)

accuracy_vec(truth, estimate, na_rm = TRUE, ...)

Arguments
data Either a data.frame containing the truth and estimate columns, or a table/matrix
where the true class results should be in the columns of the table.
...
Not currently used.
truth The column identifier for the true class results (that is a factor). This should be
an unquoted column name although this argument is passed by expression and
supports quasiquotation (you can unquote column names). For _vec() functions,
a factor vector.
estimate The column identifier for the predicted class results (that is also factor). As
with truth this can be specified different ways but the primary method is to use
an unquoted variable name. For _vec() functions, a factor vector.
na_rm A logical value indicating whether NA values should be stripped before the
computation proceeds.

Value
A tibble with columns .metric, .estimator, and .estimate and 1 row of values.
For grouped data frames, the number of rows returned will be the same as the number of groups.
For accuracy_vec(), a single numeric value (or NA).
Multiclass

Accuracy extends naturally to multiclass scenarios. Because of this, macro and micro averaging are not implemented.

Author(s)

Max Kuhn

Other class metrics: bal_accuracy(), detection_prevalence(), f_meas(), j_index(), kap(), mcc(), npv(), ppv(), precision(), recall(), sens(), spec()

Examples

library(dplyr)
data("two_class_example")data("hpc_cv")

# Two class
accuracy(two_class_example, truth, predicted)

# Multiclass
# accuracy() has a natural multiclass extension
hpc_cv %>%
  filter(Resample == "Fold01") %>%
  accuracy(obs, pred)

# Groups are respected
hpc_cv %>%
  group_by(Resample) %>%
  accuracy(obs, pred)

average_precision Area under the precision recall curve

Description

average_precision() is an alternative to pr_auc() that avoids any ambiguity about what the value of precision should be when recall == 0 and there are not yet any false positive values (some say it should be 0, others say 1, others say undefined).

It computes a weighted average of the precision values returned from pr_curve(), where the weights are the increase in recall from the previous threshold. See pr_curve() for the full curve.
average_precision

Usage

average_precision(data, ...)

## S3 method for class 'data.frame'
average_precision(
  data,
  truth,
  ...
)

average_precision_vec(
  truth,
  estimate,
  estimator = NULL,
  na_rm = TRUE,
  event_level = yardstick_event_level()
)

Arguments

data: A data.frame containing the truth and estimate columns.

...: A set of unquoted column names or one or more dplyr selector functions to
choose which variables contain the class probabilities. If truth is binary, only
1 column should be selected. Otherwise, there should be as many columns as
factor levels of truth.

truth: The column identifier for the true class results (that is a factor). This should be
an unquoted column name although this argument is passed by expression and
supports quasiquotation (you can unquote column names). For_vec() functions,
a factor vector.

estimator: One of "binary", "macro", or "macro_weighted" to specify the type of aver-
ing to be done. "binary" is only relevant for the two class case. The other
two are general methods for calculating multiclass metrics. The default will
automatically choose "binary" or "macro" based on truth.

na_rm: A logical value indicating whether NA values should be stripped before the
computation proceeds.

event_level: A single string. Either "first" or "second" to specify which level of truth
to consider as the "event". This argument is only applicable when estimator =
"binary". The default uses an internal helper that generally defaults to "first",
however, if the deprecated global option yardstick.event_first is set, that
will be used instead with a warning.

estimate: If truth is binary, a numeric vector of class probabilities corresponding to the
"relevant" class. Otherwise, a matrix with as many columns as factor levels of
truth. It is assumed that these are in the same order as the levels of truth.
The computation for average precision is a weighted average of the precision values. Assuming you have \( n \) rows returned from \( \text{pr_curve()} \), it is a sum from 2 to \( n \), multiplying the precision value \( p_i \) by the increase in recall over the previous threshold, \( r_i - r_{i-1} \).

\[
AP = \sum (r_i - r_{i-1}) * p_i
\]

By summing from 2 to \( n \), the precision value \( p_1 \) is never used. While \( \text{pr_curve()} \) returns a value for \( p_1 \), it is technically undefined as \( \frac{tp}{tp + fp} \) with \( tp = 0 \) and \( fp = 0 \). A common convention is to use 1 for \( p_1 \), but this metric has the nice property of avoiding the ambiguity. On the other hand, \( r_1 \) is well defined as long as there are some events (\( p \)), and it is \( \frac{tp}{p} \) with \( tp = 0 \), so \( r_1 = 0 \).

When \( p_1 \) is defined as 1, the \( \text{average_precision()} \) and \( \text{roc_auc()} \) values are often very close to one another.

**Value**

A tibble with columns \.metric\, .estimator\, and \.estimate\ and 1 row of values.

For grouped data frames, the number of rows returned will be the same as the number of groups.

For \( \text{average_precision_vec()} \), a single numeric value (or NA).

**Multiclass**

Macro and macro-weighted averaging is available for this metric. The default is to select macro averaging if a truth factor with more than 2 levels is provided. Otherwise, a standard binary calculation is done. See vignette("multiclass","yardstick") for more information.

**Relevant Level**

There is no common convention on which factor level should automatically be considered the "event" or "positive" result when computing binary classification metrics. In yardstick, the default is to use the first level. To alter this, change the argument \text{event_level} to "second" to consider the last level of the factor the level of interest. For multiclass extensions involving one-vs-all comparisons (such as macro averaging), this option is ignored and the "one" level is always the relevant result.

**See Also**

\( \text{pr_curve()} \) for computing the full precision recall curve.

\( \text{pr_auc()} \) for computing the area under the precision recall curve using the trapezoidal rule.

Other class probability metrics: \( \text{classification_cost()}\, \text{gain_capture()}\, \text{mn_log_loss()}\, \text{pr_auc()}\, \text{roc_auc()}\, \text{roc_aunp()}\, \text{roc_aunu()} \)
Examples

# Two class example

# `truth` is a 2 level factor. The first level is `"Class1"`, which is the
# "event of interest" by default in yardstick. See the Relevant Level
# section above.

```
data(two_class_example)
```

# Binary metrics using class probabilities take a factor `truth` column,
# and a single class probability column containing the probabilities of
# the event of interest. Here, since `"Class1"` is the first level of
# "truth", it is the event of interest and we pass in probabilities for it.

```
average_precision(two_class_example, truth, Class1)
```

# Multiclass example

# `obs` is a 4 level factor. The first level is `"VF"`, which is the
# "event of interest" by default in yardstick. See the Relevant Level
# section above.

```
data(hpc_cv)
```

# You can use the `col1:colN` tidyselect syntax

```
library(dplyr)
hpc_cv %>%
  filter(Resample == "Fold01") %>%
  average_precision(obs, VF:L)
```

# Change the first level of `obs` from `"VF"` to `"M"` to alter the
# event of interest. The class probability columns should be supplied
# in the same order as the levels.

```
hpc_cv %>%
  filter(Resample == "Fold01") %>%
  mutate(obs = relevel(obs, "M")) %>%
  average_precision(obs, M, VF:L)
```

# Groups are respected

```
hpc_cv %>%
  group_by(Resample) %>%
  average_precision(obs, VF:L)
```

# Weighted macro averaging

```
hpc_cv %>%
  group_by(Resample) %>%
  average_precision(obs, VF:L, estimator = "macro_weighted")
```

# Vector version

# Supply a matrix of class probabilities

```
fold1 <- hpc_cv %>%
  filter(Resample == "Fold01")
```
Balanced accuracy is computed here as the average of `sens()` and `spec()`.

**Usage**

```r
bal_accuracy(data, ...)  
## S3 method for class 'data.frame'
bal_accuracy(
  data,
  truth,
  estimate,
  estimator = NULL,
  na.rm = TRUE,
  event_level = yardstick_event_level(),
  ...
)
```

```r
bal_accuracy_vec(
  truth,
  estimate,
  estimator = NULL,
  na.rm = TRUE,
  event_level = yardstick_event_level(),
  ...
)
```

**Arguments**

- `data` Either a `data.frame` containing the `truth` and `estimate` columns, or a `table/matrix` where the true class results should be in the columns of the table.
- `...` Not currently used.
The column identifier for the true class results (that is a factor). This should be an unquoted column name although this argument is passed by expression and supports quasiquotation (you can unquote column names). For _vec() functions, a factor vector.

estimate

The column identifier for the predicted class results (that is also factor). As with truth this can be specified different ways but the primary method is to use an unquoted variable name. For _vec() functions, a factor vector.

estimator

One of: "binary", "macro", "macro_weighted", or "micro" to specify the type of averaging to be done. "binary" is only relevant for the two class case. The other three are general methods for calculating multiclass metrics. The default will automatically choose "binary" or "macro" based on estimate.

na_rm

A logical value indicating whether NA values should be stripped before the computation proceeds.

event_level

A single string. Either "first" or "second" to specify which level of truth to consider as the "event". This argument is only applicable when estimator = "binary". The default uses an internal helper that generally defaults to "first", however, if the deprecated global option yardstick.event_first is set, that will be used instead with a warning.

Value

A tibble with columns .metric, .estimator, and .estimate and 1 row of values. For grouped data frames, the number of rows returned will be the same as the number of groups. For bal_accuracy_vec(), a single numeric value (or NA).

Relevant Level

There is no common convention on which factor level should automatically be considered the "event" or "positive" result when computing binary classification metrics. In yardstick, the default is to use the first level. To alter this, change the argument event_level to "second" to consider the last level of the factor the level of interest. For multiclass extensions involving one-vs-all comparisons (such as macro averaging), this option is ignored and the "one" level is always the relevant result.

Multiclass

Macro, micro, and macro-weighted averaging is available for this metric. The default is to select macro averaging if a truth factor with more than 2 levels is provided. Otherwise, a standard binary calculation is done. See vignette("multiclass","yardstick") for more information.

bal_accuracy_vec(
  two_class_example$truth,
  two_class_example$predicted,
  event_level = "second"
)

---

ccc  Concordance correlation coefficient

Description

Calculate the concordance correlation coefficient.

Usage

ccc(data, ...)

## S3 method for class 'data.frame'
ccc(data, truth, estimate, bias = FALSE, na_rm = TRUE, ...)
ccc_vec(truth, estimate, bias = FALSE, na_rm = TRUE, ...)

Arguments

- **data**: A data.frame containing the truth and estimate columns.
- **...**: Not currently used.
- **truth**: The column identifier for the true results (that is numeric). This should be an unquoted column name although this argument is passed by expression and supports quasiquotation (you can unquote column names). For _vec() functions, a numeric vector.
- **estimate**: The column identifier for the predicted results (that is also numeric). As with truth this can be specified different ways but the primary method is to use an unquoted variable name. For _vec() functions, a numeric vector.
- **bias**: A logical; should the biased estimate of variance be used (as is Lin (1989))? Defaults to FALSE.
- **na_rm**: A logical value indicating whether NA values should be stripped before the computation proceeds. Defaults to TRUE.

Details

- **ccc()**: is a metric of both consistency/correlation and accuracy, while metrics such as `rmse()` are strictly for accuracy and metrics such as `rsq()` are strictly for consistency/correlation.

Value

- A tibble with columns `.metric`, `.estimator`, and `.estimate` and 1 row of values.
- For grouped data frames, the number of rows returned will be the same as the number of groups.
- For `ccc_vec()`, a single numeric value (or `NA`).

classification_cost  Costs function for poor classification

**Description**

classification_cost() calculates the cost of a poor prediction based on user-defined costs. The costs are multiplied by the estimated class probabilities and the mean cost is returned.

**Usage**

classification_cost(data, ...)

  ## S3 method for class 'data.frame'
classification_cost(
  data,
  truth,
  ...,
  costs = NULL,
  ...)
classification_cost

    na_rm = TRUE,
    event_level = yardstick_event_level()

)

classification_cost_vec(
    truth,  
estimate,
    costs = NULL,
    na_rm = TRUE,
    event_level = yardstick_event_level(),
    ...
)

Arguments

data

A data.frame containing the truth and estimate columns.

...

A set of unquoted column names or one or more dplyr selector functions to choose which variables contain the class probabilities. If truth is binary, only 1 column should be selected. Otherwise, there should be as many columns as factor levels of truth.

truth

The column identifier for the true class results (that is a factor). This should be an unquoted column name although this argument is passed by expression and supports quasiquotation (you can unquote column names). For_vec() functions, a factor vector.

costs

A data frame with columns "truth", "estimate", and "cost".

"truth" and "estimate" should be character columns containing unique combinations of the levels of the truth factor.

"costs" should be a numeric column representing the cost that should be applied when the "estimate" is predicted, but the true result is "truth".

It is often the case that when "truth" == "estimate", the cost is zero (no penalty for correct predictions).

If any combinations of the levels of truth are missing, their costs are assumed to be zero.

If NULL, equal costs are used, applying a cost of 0 to correct predictions, and a cost of 1 to incorrect predictions.

na_rm

A logical value indicating whether NA values should be stripped before the computation proceeds.

event_level

A single string. Either "first" or "second" to specify which level of truth to consider as the "event". This argument is only applicable when estimator = "binary". The default uses an internal helper that generally defaults to "first", however, if the deprecated global option yardstick.event_first is set, that will be used instead with a warning.

estimate

If truth is binary, a numeric vector of class probabilities corresponding to the "relevant" class. Otherwise, a matrix with as many columns as factor levels of truth. It is assumed that these are in the same order as the levels of truth.
Details
As an example, suppose that there are three classes: "A", "B", and "C". Suppose there is a truly "A" observation with class probabilities $A = 0.3$, $B = 0.3$, $C = 0.4$. Suppose that, when the true result is class "A", the costs for each class were $A = 0$, $B = 5$, $C = 10$, penalizing the probability of incorrectly predicting "C" more than predicting "B". The cost for this prediction would be $0.3 \times 0 + 0.3 \times 5 + 0.4 \times 10$. This calculation is done for each sample and the individual costs are averaged.

Value
A tibble with columns .metric, .estimator, and .estimate and 1 row of values.
For grouped data frames, the number of rows returned will be the same as the number of groups.
For class_cost_vec(), a single numeric value (or NA).

conf_mat

Confusion Matrix for Categorical Data

Description

Calculates a cross-tabulation of observed and predicted classes.

Usage

conf_mat(data, ...)

## S3 method for class 'data.frame'
conf_mat(data, truth, estimate, dnn = c("Prediction", "Truth"), ...)

## S3 method for class 'conf_mat'
tidy(x, ...)
Arguments

- `data`: A data frame or a `base::table()`. 
- `...`: Options to pass to `base::table()` (not including `dnn`). This argument is not currently used for the tidy method.
- `truth`: The column identifier for the true class results (that is a `factor`). This should be an unquoted column name although this argument is passed by expression and supports quasiquotation (you can unquote column names). For `_vec()` functions, a `factor` vector.
- `estimate`: The column identifier for the predicted class results (that is also `factor`). As with `truth` this can be specified different ways but the primary method is to use an unquoted variable name. For `_vec()` functions, a `factor` vector.
- `dnn`: A character vector of dimnames for the table.
- `x`: A `conf_mat` object.

Details

For `conf_mat()` objects, a broom tidy() method has been created that collapses the cell counts by cell into a data frame for easy manipulation.

There is also a `summary()` method that computes various classification metrics at once. See `summary.conf_mat()`.

There is a `ggplot2::autoplot()` method for quickly visualizing the matrix. Both a heatmap and mosaic type is implemented.

The function requires that the factors have exactly the same levels.

Value

`conf_mat()` produces an object with class `conf_mat`. This contains the table and other objects.

`tidy.conf_mat()` generates a tibble with columns `name` (the cell identifier) and `value` (the cell count).

When used on a grouped data frame, `conf_mat()` returns a tibble containing columns for the groups along with `conf_mat`, a list-column where each element is a `conf_mat` object.

See Also

- `summary.conf_mat()` for computing a large number of metrics from one confusion matrix.

Examples

```r
library(dplyr)
data("hpc_cv")

# The confusion matrix from a single assessment set (i.e. fold)
cm <- hpc_cv %>%
  filter(Resample == "Fold01") %>%
  conf_mat(obs, pred)

# Now compute the average confusion matrix across all folds in
```
# terms of the proportion of the data contained in each cell.
# First get the raw cell counts per fold using the `tidy` method
library(purrr)
library(tidyr)

cells_per_resample <- hpc_cv %>%
  group_by(Resample) %>%
  conf_mat(obs, pred) %>%
  mutate(tidied = map(conf_mat, tidy)) %>%
  unnest(tidied)

# Get the totals per resample
counts_per_resample <- hpc_cv %>%
  group_by(Resample) %>%
  summarize(total = n()) %>%
  left_join(cells_per_resample, by = "Resample") %>%
  # Compute the proportions
  mutate(prop = value/total) %>%
  group_by(name) %>%
  # Average
  summarize(prop = mean(prop))

counts_per_resample

# Now reshape these into a matrix
mean_cmat <- matrix(counts_per_resample$prop, byrow = TRUE, ncol = 4)
rownames(mean_cmat) <- levels(hpc_cv$obs)
colnames(mean_cmat) <- levels(hpc_cv$obs)

round(mean_cmat, 3)

# The confusion matrix can quickly be visualized using autoplot()
library(ggplot2)

autoplot(cm, type = "mosaic")
autoplot(cm, type = "heatmap")

detection_prevalence  

**Detection prevalence**

Description

Detection prevalence is defined as the number of predicted positive events (both true positive and false positive) divided by the total number of predictions.

Usage

detection_prevalence(data, ...)
## detection_prevalence

```r
## S3 method for class 'data.frame'
detection_prevalence(
  data,
  truth,
  estimate,
  estimator = NULL,
  na_rm = TRUE,
  event_level = yardstick_event_level(),
  ...
)

detection_prevalence_vec(
  truth,
  estimate,
  estimator = NULL,
  na_rm = TRUE,
  event_level = yardstick_event_level(),
  ...
)
```

### Arguments

- **data**
  
  Either a `data.frame` containing the `truth` and `estimate` columns, or a `table/matrix` where the true class results should be in the columns of the table.

- **truth**
  
  The column identifier for the true class results (that is a `factor`). This should be an unquoted column name although this argument is passed by expression and supports quasiquotation (you can unquote column names). For _vec() functions, a `factor` vector.

- **estimate**
  
  The column identifier for the predicted class results (that is also `factor`). As with truth this can be specified different ways but the primary method is to use an unquoted variable name. For _vec() functions, a `factor` vector.

- **estimator**
  
  One of: "binary", "macro", "macro_weighted", or "micro" to specify the type of averaging to be done. "binary" is only relevant for the two class case. The other three are general methods for calculating multiclass metrics. The default will automatically choose "binary" or "macro" based on `estimate`.

- **na_rm**
  
  A logical value indicating whether NA values should be stripped before the computation proceeds.

- **event_level**
  
  A single string. Either "first" or "second" to specify which level of truth to consider as the "event". This argument is only applicable when estimator = "binary". The default uses an internal helper that generally defaults to "first", however, if the deprecated global option `yardstick.event_first` is set, that will be used instead with a warning.

### Value

A tibble with columns `.metric`, `.estimator`, and `.estimate` and 1 row of values.
For grouped data frames, the number of rows returned will be the same as the number of groups. For detection_prevalence_vec(), a single numeric value (or NA).

Relevant Level

There is no common convention on which factor level should automatically be considered the "event" or "positive" result when computing binary classification metrics. In yardstick, the default is to use the first level. To alter this, change the argument event_level to "second" to consider the last level of the factor the level of interest. For multiclass extensions involving one-vs-all comparisons (such as macro averaging), this option is ignored and the "one" level is always the relevant result.

Multiclass

Macro, micro, and macro-weighted averaging is available for this metric. The default is to select macro averaging if a truth factor with more than 2 levels is provided. Otherwise, a standard binary calculation is done. See vignette("multiclass","yardstick") for more information.

---

f_meas | F Measure

**Description**

These functions calculate the `f_meas()` of a measurement system for finding relevant documents compared to reference results (the truth regarding relevance). Highly related functions are `recall()` and `precision()`.

**Usage**

```
f_meas(data, ...)
```  
```
## S3 method for class 'data.frame'
f_meas(
    data,
    truth,
    estimate,
    beta = 1,
    estimator = NULL,
    na_rm = TRUE,
    event_level = yardstick_event_level(),
    ...
)
```

```
f_meas_vec(
    truth,
    estimate,
    beta = 1,
    estimator = NULL,
    na_rm = TRUE,
    event_level = yardstick_event_level(),
    ...
)
```
Arguments

data Either a data.frame containing the truth and estimate columns, or a table/matrix where the true class results should be in the columns of the table.

... Not currently used.

truth The column identifier for the true class results (that is a factor). This should be an unquoted column name although this argument is passed by expression and supports quasiquotation (you can unquote column names). For _vec() functions, a factor vector.

estimate The column identifier for the predicted class results (that is also factor). As with truth this can be specified different ways but the primary method is to use an unquoted variable name. For _vec() functions, a factor vector.

beta A numeric value used to weight precision and recall. A value of 1 is traditionally used and corresponds to the harmonic mean of the two values but other values weight recall beta times more important than precision.

estimator One of: "binary", "macro", "macro_weighted", or "micro" to specify the type of averaging to be done. "binary" is only relevant for the two class case. The other three are general methods for calculating multiclass metrics. The default will automatically choose "binary" or "macro" based on estimate.

na_rm A logical value indicating whether NA values should be stripped before the computation proceeds.

event_level A single string. Either "first" or "second" to specify which level of truth to consider as the "event". This argument is only applicable when estimator = "binary". The default uses an internal helper that generally defaults to "first", however, if the deprecated global option yardstick.event_first is set, that will be used instead with a warning.

Details

The measure "F" is a combination of precision and recall (see below).

Value

A tibble with columns .metric, .estimator, and .estimate and 1 row of values.

For grouped data frames, the number of rows returned will be the same as the number of groups.

For f_meas_vec(), a single numeric value (or NA).

Relevant Level

There is no common convention on which factor level should automatically be considered the "event" or "positive" result when computing binary classification metrics. In yardstick, the default is to use the first level. To alter this, change the argument event_level to "second" to consider the last level of the factor the level of interest. For multiclass extensions involving one-vs-all comparisons (such as macro averaging), this option is ignored and the "one" level is always the relevant result.
Multiclass

Macro, micro, and macro-weighted averaging is available for this metric. The default is to select macro averaging if a truth factor with more than 2 levels is provided. Otherwise, a standard binary calculation is done. See vignette("multiclass","yardstick") for more information.

Implementation

Suppose a 2x2 table with notation:

<table>
<thead>
<tr>
<th></th>
<th>Reference</th>
<th>Predicted</th>
</tr>
</thead>
<tbody>
<tr>
<td>Relevant</td>
<td>A</td>
<td>B</td>
</tr>
<tr>
<td>Irrelevant</td>
<td>C</td>
<td>D</td>
</tr>
</tbody>
</table>

The formulas used here are:

\[
\text{recall} = \frac{A}{A + C}
\]

\[
\text{precision} = \frac{A}{A + B}
\]

\[
F_{\text{meas}} = \frac{(1 + \beta^2) \times \text{precision} \times \text{recall}}{(\beta^2 \times \text{precision}) + \text{recall}}
\]

See the references for discussions of the statistics.

gain_capture | Gain capture

**Description**

gain_capture() is a measure of performance similar to an AUC calculation, but applied to a gain curve.

**Usage**

gain_capture(data, ...)

## S3 method for class 'data.frame'
gain_capture(
  data,
  truth,
  ..., 
  estimator = NULL, 
  na.rm = TRUE,

```r
event_level = yardstick_event_level()
}

gain_capture_vec(
  truth,
  estimate,
  estimator = NULL,
  na_rm = TRUE,
  event_level = yardstick_event_level(),
  ...
)
```

### Arguments

- **data**
  A `data.frame` containing the `truth` and `estimate` columns.

- **...**
  A set of unquoted column names or one or more `dplyr` selector functions to choose which variables contain the class probabilities. If `truth` is binary, only 1 column should be selected. Otherwise, there should be as many columns as factor levels of `truth`.

- **truth**
  The column identifier for the true class results (that is a `factor`). This should be an unquoted column name although this argument is passed by expression and supports **quasiquotation** (you can unquote column names). For `.vec()` functions, a `factor` vector.

- **estimator**
  One of "binary", "macro", or "macro_weighted" to specify the type of averaging to be done. "binary" is only relevant for the two class case. The other two are general methods for calculating multiclass metrics. The default will automatically choose "binary" or "macro" based on `truth`.

- **na_rm**
  A logical value indicating whether NA values should be stripped before the computation proceeds.

- **event_level**
  A single string. Either "first" or "second" to specify which level of `truth` to consider as the "event". This argument is only applicable when `estimator` = "binary". The default uses an internal helper that generally defaults to "first", however, if the deprecated global option `yardstick.event_first` is set, that will be used instead with a warning.

- **estimate**
  If `truth` is binary, a numeric vector of class probabilities corresponding to the "relevant" class. Otherwise, a matrix with as many columns as factor levels of `truth`. **It is assumed that these are in the same order as the levels of `truth`**.

### Details

`gain_capture()` calculates the area under the gain curve, but above the baseline, and then divides that by the area under a perfect gain curve, but above the baseline. It is meant to represent the amount of potential gain "captured" by the model.

The `gain_capture()` metric is identical to the accuracy ratio (AR), which is also sometimes called the gini coefficient. These two are generally calculated on a cumulative accuracy profile curve, but this is the same as a gain curve. See the Engelmann reference for more information.
**Value**

A tibble with columns `metric`, `estimator`, and `estimate` and 1 row of values.

For grouped data frames, the number of rows returned will be the same as the number of groups.

For `gain_capture_vec()`, a single numeric value (or NA).

**Relevant Level**

There is no common convention on which factor level should automatically be considered the "event" or "positive" result when computing binary classification metrics. In yardstick, the default is to use the first level. To alter this, change the argument `event_level` to "second" to consider the last level of the factor the level of interest. For multiclass extensions involving one-vs-all comparisons (such as macro averaging), this option is ignored and the "one" level is always the relevant result.

**Multiclass**

Macro and macro-weighted averaging is available for this metric. The default is to select macro averaging if a truth factor with more than 2 levels is provided. Otherwise, a standard binary calculation is done. See vignette("multiclass","yardstick") for more information.

**Examples**

```r
# Two class example

data(two_class_example)

data(two_class_example)

# Binary metrics using class probabilities take a factor 'truth' column,
# and a single class probability column containing the probabilities of
# the event of interest. Here, since '"Class1"' is the first level of
```
# "truth", it is the event of interest and we pass in probabilities for it.
gain_capture(two_class_example, truth, Class1)

# Multiclass example

# `obs` is a 4 level factor. The first level is "VF", which is the
# "event of interest" by default in yardstick. See the Relevant Level
# section above.
data(hpc_cv)

# You can use the col1:colN tidyselect syntax
library(dplyr)
hpc_cv %>%
  filter(Resample == "Fold01") %>%
gain_capture(obs, VF:L)

# Change the first level of `obs` from "VF" to "M" to alter the
# event of interest. The class probability columns should be supplied
# in the same order as the levels.
hpc_cv %>%
  filter(Resample == "Fold01") %>%
  mutate(obs = relevel(obs, "M")) %>%
gain_capture(obs, M, VF:L)

# Groups are respected
hpc_cv %>%
  group_by(Resample) %>%
gain_capture(obs, VF:L)

# Weighted macro averaging
hpc_cv %>%
  group_by(Resample) %>%
gain_capture(obs, VF:L, estimator = "macro_weighted")

# Vector version
# Supply a matrix of class probabilities
fold1 <- hpc_cv %>%
  filter(Resample == "Fold01")

gain_capture_vec(
  truth = fold1$obs,
  matrix(
    c(fold1$VF, fold1$F, fold1$M, fold1$L),
    ncol = 4
  )
)

# Visually, this represents the area under the black curve, but above the
# 45 degree line, divided by the area of the shaded triangle.
```
library(ggplot2)
autoplot(gain_curve(two_class_example, truth, Class1))

---

### gain_curve

#### Gain curve

**Description**

gain_curve() constructs the full gain curve and returns a tibble. See gain_capture() for the relevant area under the gain curve. Also see lift_curve() for a closely related concept.

#### Usage

gain_curve(data, ...)

```r
## S3 method for class 'data.frame'
gain_curve(
  data,
  truth,
  ...,
  na_rm = TRUE,
  event_level = yardstick_event_level()
)
```

#### Arguments

- **data**: A `data.frame` containing the truth and estimate columns.
- **...**: A set of unquoted column names or one or more `dplyr` selector functions to choose which variables contain the class probabilities. If truth is binary, only 1 column should be selected. Otherwise, there should be as many columns as factor levels of truth.
- **truth**: The column identifier for the true class results (that is a factor). This should be an unquoted column name although this argument is passed by expression and supports `quasiquotation` (you can unquote column names). For `_vec()` functions, a factor vector.
- **na_rm**: A logical value indicating whether NA values should be stripped before the computation proceeds.
- **event_level**: A single string. Either "first" or "second" to specify which level of truth to consider as the "event". This argument is only applicable when estimator = "binary". The default uses an internal helper that generally defaults to "first", however, if the deprecated global option yardstick.event_first is set, that will be used instead with a warning.
Details

There is a `ggplot2::autoplot()` method for quickly visualizing the curve. This works for binary and multiclass output, and also works with grouped data (i.e. from resamples). See the examples. The greater the area between the gain curve and the baseline, the better the model.

Gain curves are identical to CAP curves (cumulative accuracy profile). See the Engelmann reference for more information on CAP curves.

Value

A tibble with class `gain_df` or `gain_grouped_df` having columns:

- `.n` - The index of the current sample.
- `.n_events` - The index of the current unique sample. Values with repeated `estimate` values are given identical indices in this column.
- `.percent_tested` - The cumulative percentage of values tested.
- `.percent_found` - The cumulative percentage of true results relative to the total number of true results.

Gain and Lift Curves

The motivation behind cumulative gain and lift charts is as a visual method to determine the effectiveness of a model when compared to the results one might expect without a model. As an example, without a model, if you were to advertise to a random 10\% to capture 10\% advertised to your entire customer base. Given a model that predicts which customers are more likely to respond, the hope is that you can more accurately target 10\% > 10\%

The calculation to construct gain curves is as follows:

1. `truth` and `estimate` are placed in descending order by the `estimate` values (estimate here is a single column supplied in ...).
2. The cumulative number of samples with true results relative to the entire number of true results are found. This is the y-axis in a gain chart.

Multiclass

If a multiclass `truth` column is provided, a one-vs-all approach will be taken to calculate multiple curves, one per level. In this case, there will be an additional column, `.level`, identifying the "one" column in the one-vs-all calculation.

Relevant Level

There is no common convention on which factor level should automatically be considered the "event" or "positive" result when computing binary classification metrics. In `yardstick`, the default is to use the first level. To alter this, change the argument `event_level` to "second" to consider the last level of the factor the level of interest. For multiclass extensions involving one-vs-all comparisons (such as macro averaging), this option is ignored and the "one" level is always the relevant result.

Examples
```r
# Two class example

# 'truth' is a 2 level factor. The first level is "Class1", which is the
# "event of interest" by default in yardstick. See the Relevant Level
# section above.
data(two_class_example)

# Binary metrics using class probabilities take a factor 'truth' column,
# and a single class probability column containing the probabilities of
# the event of interest. Here, since "Class1" is the first level of
# "truth", it is the event of interest and we pass in probabilities for it.
gain_curve(two_class_example, truth, Class1)

# 'autoplot()
library(ggplot2)
library(dplyr)

# Use autoplot to visualize
# The top left hand corner of the grey triangle is a "perfect" gain curve
autoplot(gain_curve(two_class_example, truth, Class1))

# Multiclass one-vs-all approach
# One curve per level
hpc_cv %>%
  filter(Resample == "Fold01") %>%
gain_curve(obs, VF:L) %>%
  autoplot()

# Same as above, but will all of the resamples
# The resample with the minimum (farthest to the left) "perfect" value is
# used to draw the shaded region
hpc_cv %>%
```
get_weights

get_weights

Developer helpers

Description

Helpers to be used alongside `metric_vec_template()` and `metric_summarizer()` when creating new metrics. See vignette("custom-metrics", "yardstick") for more information.

Usage

group_by(Resample) %>%
gain_curve(obs, VF:L) %>%
autoplot()

group_by(Resample) %>%
gain_curve(obs, VF:L) %>%
autoplot()

group_by(Resample) %>%
gain_curve(obs, VF:L) %>%
autoplot()

group_by(Resample) %>%
gain_curve(obs, VF:L) %>%
autoplot()

get_weights(data, estimator)

finalize_estimator(x, estimator = NULL, metric_class = "default")

finalize_estimator_internal(metric_dispatcher, x, estimator)

dots_to_estimate(data, ...)

validate_estimator(estimator, estimator_override = NULL)

Arguments

data A table with truth values as columns and predicted values as rows.
estimator Either NULL for auto-selection, or a single character for the type of estimator to use.
x The column used to autoselect the estimator. This is generally the truth column, but can also be a table if your metric has table methods.
metric_class A single character of the name of the metric to autoselect the estimator for. This should match the method name created for `finalize_estimator_internal()`.
metric_dispatcher A simple dummy object with the class provided to `metric_class`. This is created and passed along for you.
... A set of unquoted column names or one or more dplyr selector functions to choose which variables contain the class probabilities. If truth is binary, only 1 column should be selected. Otherwise, there should be as many columns as factor levels of truth.
estimator_override A character vector overriding the default allowed estimator list of c("binary", "macro", "micro", "macro_weighted"). Set this if your classification estimator does not support all of these methods.
Weight Calculation

get_weights() accepts a confusion matrix and an estimator of type "macro", "micro", or "macro_weighted" and returns the correct weights. It is useful when creating multiclass metrics.

Estimator Selection

finalize_estimator() is the engine for auto-selection of estimator based on the type of \( x \). Generally \( x \) is the truth column. This function is called from the vector method of your metric.

finalize_estimator_internal() is an S3 generic that you should extend for your metric if it does not implement only the following estimator types: "binary", "macro", "micro", and "macro_weighted". If your metric does support all of these, the default version of finalize_estimator_internal() will autoselect estimator appropriately. If you need to create a method, it should take the form: finalize_estimator_internal.metric_name. Your method for finalize_estimator_internal() should do two things:

1. If estimator is NULL, autoselect the estimator based on the type of \( x \) and return a single character for the estimator.
2. If estimator is not NULL, validate that it is an allowed estimator for your metric and return it.

If you are using the default for finalize_estimator_internal(), the estimator is selected using the following heuristics:

1. If estimator is not NULL, it is validated and returned immediately as no auto-selection is needed.
2. If \( x \) is a:
   - factor - Then "binary" is returned if it has 2 levels, otherwise "macro" is returned.
   - numeric - Then "binary" is returned.
   - table - Then "binary" is returned if it has 2 columns, otherwise "macro" is returned.
   - matrix - Then "macro" is returned.

Dots -> Estimate

dots_to_estimate() is useful with class probability metrics that take ... rather than estimate as an argument. It constructs either a single name if 1 input is provided to ... or it constructs a quosure where the expression constructs a matrix of as many columns as are provided to ... These are eventually evaluated in the summarise() call in metric_summarizer() and evaluate to either a vector or a matrix for further use in the underlying vector functions.

Estimator Validation

validate_estimator() is called from your metric specific method of finalize_estimator_internal() and ensures that a user provided estimator is of the right format and is one of the allowed values.

*Multiclass Probability Predictions*

---

**Description**

Multiclass Probability Predictions

**Details**

This data frame contains the predicted classes and class probabilities for a linear discriminant analysis model fit to the HPC data set from Kuhn and Johnson (2013). These data are the assessment sets from a 10-fold cross-validation scheme. The data column columns for the true class (`obs`), the class prediction (`pred`) and columns for each class probability (columns `VF`, `F`, `M`, and `L`). Additionally, a column for the resample indicator is included.

**Value**

| hpc_cv | a data frame |

**Source**

**Examples**

data(hpc_cv)  
str(hpc_cv)  

# `obs` is a 4 level factor. The first level is `"VF"`, which is the  
# "event of interest" by default in yardstick. See the Relevant Level  
# section in any classification function (such as `?pr_auc`) to see how  
# to change this.  
levels(hpc_cv$obs)

---

**huber_loss**  
*Huber loss*

---

**Description**

Calculate the Huber loss, a loss function used in robust regression. This loss function is less sensitive to outliers than `rmse()`. This function is quadratic for small residual values and linear for large residual values.
Usage

huber_loss(data, ...)

## S3 method for class 'data.frame'
huber_loss(data, truth, estimate, delta = 1, na_rm = TRUE, ...)

huber_loss_vec(truth, estimate, delta = 1, na_rm = TRUE, ...)

Arguments

data A data.frame containing the truth and estimate columns.

... Not currently used.

truth The column identifier for the true results (that is numeric). This should be an unquoted column name although this argument is passed by expression and supports quasiquotation (you can unquote column names). For _vec() functions, a numeric vector.

estimate The column identifier for the predicted results (that is also numeric). As with truth this can be specified different ways but the primary method is to use an unquoted variable name. For _vec() functions, a numeric vector.

delta A single numeric value. Defines the boundary where the loss function transitions from quadratic to linear. Defaults to 1.

na_rm A logical value indicating whether NA values should be stripped before the computation proceeds.

Value

A tibble with columns .metric, .estimator, and .estimate and 1 row of values.

For grouped data frames, the number of rows returned will be the same as the number of groups.

For huber_loss_vec(), a single numeric value (or NA).

### iic

**Index of ideality of correlation**

**Description**

Calculate the index of ideality of correlation. This metric has been studied in QSPR/QSAR models as a good criterion for the predictive potential of these models. It is highly dependent on the correlation coefficient as well as the mean absolute error.

Note the application of IIC is useless under two conditions:

- When the negative mean absolute error and positive mean absolute error are both zero.
- When the outliers are symmetric. Since outliers are context dependent, please use your own checks to validate whether this restriction holds and whether the resulting IIC has interpretative value.

The IIC is seen as an alternative to the traditional correlation coefficient and is in the same units as the original data.

**Usage**

```r
iic(data, ...)
```

## S3 method for class 'data.frame'
iic(data, truth, estimate, na_rm = TRUE, ...)
iic_vec(truth, estimate, na_rm = TRUE, ...)

---
Arguments

- **data**: A data.frame containing the truth and estimate columns.
- **truth**: The column identifier for the true results (that is numeric). This should be an unquoted column name although this argument is passed by expression and supports quasiquotation (you can unquote column names). For _vec() functions, a numeric vector.
- **estimate**: The column identifier for the predicted results (that is also numeric). As with truth this can be specified different ways but the primary method is to use an unquoted variable name. For _vec() functions, a numeric vector.
- **na_rm**: A logical value indicating whether NA values should be stripped before the computation proceeds.

Value

A tibble with columns .metric, .estimator, and .estimate and 1 row of values.

For grouped data frames, the number of rows returned will be the same as the number of groups. For iic_vec(), a single numeric value (or NA).

### `j_index`

<table>
<thead>
<tr>
<th><strong>J-index</strong></th>
</tr>
</thead>
</table>

**Description**

Youden’s J statistic is defined as:

\[
\text{sens()} + \text{spec()} - 1
\]

A related metric is Informedness, see the Details section for the relationship.

**Usage**

```r
j_index(data, ...)
```

## S3 method for class 'data.frame'

```r
call(j_index(  
data,  
  truth,  
  estimate,  
estimator = NULL,  
  na.rm = TRUE,  
  event_level = yardstick_event_level(),  
  ...  
))
```

```r
j_index_vec(  
  truth,  
estimate,  
estimator = NULL,
)```
\[\text{na.rm} = \text{TRUE}, \]
\[\text{event.level} = \text{yardstick.event.level}(), \]
\[\text{...} \]

**Arguments**

- **data**: Either a `data.frame` containing the truth and estimate columns, or a `table/matrix` where the true class results should be in the columns of the table.

- **...**: Not currently used.

- **truth**: The column identifier for the true class results (that is a factor). This should be an unquoted column name although this argument is passed by expression and supports `quasiquotation` (you can unquote column names). For `_vec()` functions, a factor vector.

- **estimate**: The column identifier for the predicted class results (that is also factor). As with `truth` this can be specified different ways but the primary method is to use an unquoted variable name. For `_vec()` functions, a factor vector.

- **estimator**: One of: "binary", "macro", "macro_weighted", or "micro" to specify the type of averaging to be done. "binary" is only relevant for the two class case. The other three are general methods for calculating multiclass metrics. The default will automatically choose "binary" or "macro" based on `estimate`.

- **na.rm**: A logical value indicating whether NA values should be stripped before the computation proceeds.

- **event.level**: A single string. Either "first" or "second" to specify which level of truth to consider as the "event". This argument is only applicable when `estimator` = "binary". The default uses an internal helper that generally defaults to "first", however, if the deprecated global option `yardstick.event_first` is set, that will be used instead with a warning.

**Details**

The value of the J-index ranges from \([0, 1]\) and is 1 when there are no false positives and no false negatives.

The binary version of J-index is equivalent to the binary concept of Informedness. Macro-weighted J-index is equivalent to multiclass informedness as defined in Powers, David M W (2011), equation (42).

**Value**

A `tibble` with columns `.metric`, `.estimator`, and `.estimate` and 1 row of values.

For grouped data frames, the number of rows returned will be the same as the number of groups.

For `j_index_vec()`, a single numeric value (or NA).
Relevant Level

There is no common convention on which factor level should automatically be considered the "event" or "positive" result when computing binary classification metrics. In yardstick, the default is to use the first level. To alter this, change the argument event_level to "second" to consider the last level of the factor the level of interest. For multiclass extensions involving one-vs-all comparisons (such as macro averaging), this option is ignored and the "one" level is always the relevant result.

Multiclass

Macro, micro, and macro-weighted averaging is available for this metric. The default is to select macro averaging if a truth factor with more than 2 levels is provided. Otherwise, a standard binary calculation is done. See vignette("multiclass", "yardstick") for more information.

Examples

# Two class
data("two_class_example")
j_index(two_class_example, truth, predicted)

# Multiclass
library(dplyr)
data(hpc_cv)

hpc_cv %>%
  filter(Resample == "Fold01") %>%
j_index(obs, pred)

# Groups are respected
hpc_cv %>%
group_by(Resample) %>%
j_index(obs, pred)

# Weighted macro averaging
hpc_cv %>%
Kappa

## Description

Kappa is a similar measure to `accuracy()`, but is normalized by the accuracy that would be expected by chance alone and is very useful when one or more classes have large frequency distributions.

## Usage

```r
kap(data, ...)  
## S3 method for class 'data.frame'  
kap(data, truth, estimate, weighting = "none", na.rm = TRUE, ...)  
kap_vec(truth, estimate, weighting = "none", na.rm = TRUE, ...)
```

## Arguments

- `data` Either a `data.frame` containing the truth and estimate columns, or a `table/matrix` where the true class results should be in the columns of the table.
- `...` Not currently used.
- `truth` The column identifier for the true class results (that is a factor). This should be an unquoted column name although this argument is passed by expression and supports `quasiquotation` (you can unquote column names). For `_vec()` functions, a factor vector.
- `estimate` The column identifier for the predicted class results (that is also factor). As with truth this can be specified different ways but the primary method is to use an unquoted variable name. For `_vec()` functions, a factor vector.
weighting
A weighting to apply when computing the scores. One of: "none", "linear", or "quadratic". Linear and quadratic weighting penalizes mis-predictions that are "far away" from the true value. Note that distance is judged based on the ordering of the levels in truth and estimate. It is recommended to provide ordered factors for truth and estimate to explicitly code the ordering, but this is not required.
In the binary case, all 3 weightings produce the same value, since it is only ever possible to be 1 unit away from the true value.

na_rm
A logical value indicating whether NA values should be stripped before the computation proceeds.

Value
A tibble with columns .metric, .estimator, and .estimate and 1 row of values.
For grouped data frames, the number of rows returned will be the same as the number of groups.
For kap_vec(), a single numeric value (or NA).

Multiclass
Kappa extends naturally to multiclass scenarios. Because of this, macro and micro averaging are not implemented.

**lift_curve**

**Lift curve**

**Description**

`lift_curve()` constructs the full lift curve and returns a tibble. See `gain_curve()` for a closely related concept.

**Usage**

```r
lift_curve(data, ...)
```

## S3 method for class 'data.frame'
```r
lift_curve(
  data,
  truth,
  ..., 
  na_rm = TRUE,
  event_level = yardstick_event_level()
)
```

**Arguments**

- **data**
  
  A `data.frame` containing the truth and estimate columns.

- **...**
  
  A set of unquoted column names or one or more `dplyr` selector functions to choose which variables contain the class probabilities. If truth is binary, only 1 column should be selected. Otherwise, there should be as many columns as factor levels of truth.

- **truth**
  
  The column identifier for the true class results (that is a factor). This should be an unquoted column name although this argument is passed by expression and supports quasiquotation (you can unquote column names). For _vec() functions, a factor vector.

- **na_rm**
  
  A logical value indicating whether NA values should be stripped before the computation proceeds.
event_level  A single string. Either "first" or "second" to specify which level of truth to consider as the "event". This argument is only applicable when estimator = "binary". The default uses an internal helper that generally defaults to "first", however, if the deprecated global option yardstick.event_first is set, that will be used instead with a warning.

Details

There is a ggplot2::autoplot() method for quickly visualizing the curve. This works for binary and multiclass output, and also works with grouped data (i.e. from resamples). See the examples.

Value

A tibble with class lift_df or lift_grouped_df having columns:

- .n - The index of the current sample.
- .n_events - The index of the current unique sample. Values with repeated estimate values are given identical indices in this column.
- .percent_tested - The cumulative percentage of values tested.
- lift - First calculate the cumulative percentage of true results relative to the total number of true results. Then divide that by .percent_tested.

Gain and Lift Curves

The motivation behind cumulative gain and lift charts is as a visual method to determine the effectiveness of a model when compared to the results one might expect without a model. As an example, without a model, if you were to advertise to a random 10% to capture 10% advertised to your entire customer base. Given a model that predicts which customers are more likely to respond, the hope is that you can more accurately target 10% >10%

The calculation to construct lift curves is as follows:

1. truth and estimate are placed in descending order by the estimate values (estimate here is a single column supplied in ...).
2. The cumulative number of samples with true results relative to the entire number of true results are found.
3. The cumulative \ to construct the lift value. This ratio represents the factor of improvement over an uninformed model. Values >1 represent a valuable model. This is the y-axis of the lift chart.

Multiclass

If a multiclass truth column is provided, a one-vs-all approach will be taken to calculate multiple curves, one per level. In this case, there will be an additional column, .level, identifying the "one" column in the one-vs-all calculation.
Relevant Level

There is no common convention on which factor level should automatically be considered the "event" or "positive" result when computing binary classification metrics. In yardstick, the default is to use the first level. To alter this, change the argument event_level to "second" to consider the last level of the factor the level of interest. For multiclass extensions involving one-vs-all comparisons (such as macro averaging), this option is ignored and the "one" level is always the relevant result.

\textit{Mean absolute error}

\textbf{Description}

Calculate the mean absolute error. This metric is in the same units as the original data.

\textbf{Usage}

\begin{verbatim}
mae(data, ...)  
## S3 method for class 'data.frame'
mae(data, truth, estimate, na_rm = TRUE, ...)  
mae_vec(truth, estimate, na_rm = TRUE, ...)
\end{verbatim}

\textbf{Arguments}

- \texttt{data}: A \texttt{data.frame} containing the truth and estimate columns.
- \texttt{...}: Not currently used.
- \texttt{truth}: The column identifier for the true results (that is \texttt{numeric}). This should be an unquoted column name although this argument is passed by expression and supports \texttt{quasiquotation} (you can unquote column names). For \texttt{vec()} functions, a \texttt{numeric} vector.
- \texttt{estimate}: The column identifier for the predicted results (that is also \texttt{numeric}). As with truth this can be specified different ways but the primary method is to use an unquoted variable name. For \texttt{vec()} functions, a \texttt{numeric} vector.
- \texttt{na_rm}: A \texttt{logical} value indicating whether NA values should be stripped before the computation proceeds.

\textbf{Value}

A \texttt{tibble} with columns \texttt{.metric}, \texttt{.estimator}, and \texttt{.estimate} and 1 row of values.
For grouped data frames, the number of rows returned will be the same as the number of groups.
For \texttt{mae_vec()}, a single numeric value (or \texttt{NA}).

Description

Calculate the mean absolute percentage error. This metric is in relative units.
Usage

mape(data, ...)

## S3 method for class 'data.frame'
mape(data, truth, estimate, na.rm = TRUE, ...)

mape_vec(truth, estimate, na.rm = TRUE, ...)

Arguments

data A data.frame containing the truth and estimate columns.

... Not currently used.

truth The column identifier for the true results (that is numeric). This should be an unquoted column name although this argument is passed by expression and supports quasiquotation (you can unquote column names). For _vec() functions, a numeric vector.

estimate The column identifier for the predicted results (that is also numeric). As with truth this can be specified different ways but the primary method is to use an unquoted variable name. For _vec() functions, a numeric vector.

na_rm A logical value indicating whether NA values should be stripped before the computation proceeds.

Details

Note that a value of Inf is returned for mape() when the observed value is negative.

Value

A tibble with columns .metric, .estimator, and .estimate and 1 row of values.

For grouped data frames, the number of rows returned will be the same as the number of groups.

For mape_vec(), a single numeric value (or NA).

mase

Mean absolute scaled error

Description

Calculate the mean absolute scaled error. This metric is _scale independent_ and _symmetric_. It is generally used for comparing forecast error in time series settings. Due to the time series nature of this metric, it is necessary to order observations in ascending order by time.

Usage

mase(data, ...)

## S3 method for class 'data.frame'
mase(data, truth, estimate, m = 1L, mae_train = NULL, na_rm = TRUE, ...)
mase_vec(truth, estimate, m = 1L, mae_train = NULL, na_rm = TRUE, ...)
Arguments

- **data**: A data.frame containing the truth and estimate columns. Not currently used.

- **truth**: The column identifier for the true results (that is numeric). This should be an unquoted column name although this argument is passed by expression and supports `quasiquotation` (you can unquote column names). For `_vec()` functions, a numeric vector.

- **estimate**: The column identifier for the predicted results (that is also numeric). As with truth this can be specified different ways but the primary method is to use an unquoted variable name. For `_vec()` functions, a numeric vector.

- **m**: An integer value of the number of lags used to calculate the in-sample seasonal naive error. The default is used for non-seasonal time series. If each observation was at the daily level and the data showed weekly seasonality, then \( m = 7 \) would be a reasonable choice for a 7-day seasonal naive calculation.

- **mae_train**: A numeric value which allows the user to provide the in-sample seasonal naive mean absolute error. If this value is not provided, then the out-of-sample seasonal naive mean absolute error will be calculated from `truth` and will be used instead.

- **na_rm**: A logical value indicating whether NA values should be stripped before the computation proceeds.

Details

`mase()` is different from most numeric metrics. The original implementation of `mase()` calls for using the *in-sample* naive mean absolute error to compute scaled errors with. It uses this instead of the out-of-sample error because there is a chance that the out-of-sample error cannot be computed when forecasting a very short horizon (i.e. the out of sample size is only 1 or 2). However, yardstick only knows about the out-of-sample truth and estimate values. Because of this, the out-of-sample error is used in the computation by default. If the in-sample naive mean absolute error is required and known, it can be passed through in the `mae_train` argument and it will be used instead. If the in-sample data is available, the naive mean absolute error can easily be computed with `mae(data, truth, lagged_truth)`.

Value

- A tibble with columns `.metric`, `.estimator`, and `.estimate` and 1 row of values.
  For grouped data frames, the number of rows returned will be the same as the number of groups.
  For `mase_vec()`, a single numeric value (or NA).

Usage

mcc(data, ...)

## S3 method for class 'data.frame'
mcc(data, truth, estimate, na_rm = TRUE, ...)

mcc_vec(truth, estimate, na_rm = TRUE, ...)

Arguments

data

Either a data.frame containing the truth and estimate columns, or a table/matrix where the true class results should be in the columns of the table.

...

Not currently used.

truth

The column identifier for the true class results (that is a factor). This should be an unquoted column name although this argument is passed by expression and supports quasiquotation (you can unquote column names). For _vec() functions, a factor vector.

estimate

The column identifier for the predicted class results (that is also factor). As with truth this can be specified different ways but the primary method is to use an unquoted variable name. For _vec() functions, a factor vector.

na_rm

A logical value indicating whether NA values should be stripped before the computation proceeds.

Value

A tibble with columns .metric, .estimator, and .estimate and 1 row of values.

For grouped data frames, the number of rows returned will be the same as the number of groups.

For mcc_vec(), a single numeric value (or NA).

Relevant Level

There is no common convention on which factor level should automatically be considered the "event" or "positive" result when computing binary classification metrics. In yardstick, the default is to use the first level. To alter this, change the argument event_level to "second" to consider the last level of the factor the level of interest. For multiclass extensions involving one-vs-all comparisons (such as macro averaging), this option is ignored and the "one" level is always the relevant result.

Multiclass

mcc() has a known multiclass generalization and that is computed automatically if a factor with more than 2 levels is provided. Because of this, no averaging methods are provided.

**metrics**

*General Function to Estimate Performance*

**Description**

This function estimates one or more common performance estimates depending on the class of `truth` (see **Value** below) and returns them in a three column tibble.

**Usage**

```r
metrics(data, ...)
```

## S3 method for class 'data.frame'
metrics(data, truth, estimate, ...; options = list(), na_rm = TRUE)
Arguments

data A data.frame containing the truth and estimate columns and any columns specified by ...

... A set of unquoted column names or one or more dplyr selector functions to choose which variables contain the class probabilities. If truth is binary, only 1 column should be selected. Otherwise, there should be as many columns as factor levels of truth.

truth The column identifier for the true results (that is numeric or factor). This should be an unquoted column name although this argument is passed by expression and support quasiquotation (you can unquote column names).

estimate The column identifier for the predicted results (that is also numeric or factor). As with truth this can be specified different ways but the primary method is to use an unquoted variable name.

options A list of named options to pass to pROC::roc() such as smooth. These options should not include response, predictor, levels, quiet, or direction.

na_rm A logical value indicating whether NA values should be stripped before the computation proceeds.

Value

A three column tibble.

- When truth is a factor, there are rows for accuracy() and the Kappa statistic (kap()).
- When truth has two levels and 1 column of class probabilities is passed to ..., there are rows for the two class versions of mn_log_loss() and roc_auc().
- When truth has more than two levels and a full set of class probabilities are passed to ..., there are rows for the multiclass version of mn_log_loss() and the Hand Till generalization of roc_auc().
- When truth is numeric, there are rows for rmse(), rsq(), and mae().

  metrics(obs, pred, VF:L) %>%
  print(n = 40)

---

**metric_set**

Combine metric functions

**Description**

`metric_set()` allows you to combine multiple metric functions together into a new function that calculates all of them at once.

**Usage**

`metric_set(...)`

**Arguments**

`...`  

The bare names of the functions to be included in the metric set.

**Details**

All functions must be either:

- Only numeric metrics
- A mix of class metrics or class prob metrics

For instance, `rmse()` can be used with `mae()` because they are numeric metrics, but not with `accuracy()` because it is a classification metric. But `accuracy()` can be used with `roc_auc()`.

The returned metric function will have a different argument list depending on whether numeric metrics or a mix of class/prob metrics were passed in.

# Numeric metric set signature:

```r
fn(
  data,
  truth,
  estimate,
  na_rm = TRUE,
  ...
)
```

# Class / prob metric set signature:
fn(
    data,
    truth,
    ...,
    estimate,
    estimator = NULL,
    na_rm = TRUE,
    event_level = yardstick_event_level()
)

When mixing class and class prob metrics, pass in the hard predictions (the factor column) as the named argument estimate, and the soft predictions (the class probability columns) as bare column names or tidyselect selectors to ....

metrics()

Examples

library(dplyr)

# Multiple regression metrics
multi_metric <- metric_set(rmse, rsq, ccc)

# The returned function has arguments:
# fn(data, truth, estimate, na_rm = TRUE, ...)
multi_metric(solubility_test, truth = solubility, estimate = prediction)

# Groups are respected on the new metric function
class_metrics <- metric_set(accuracy, kap)

dpc_cv %>%
    group_by(Resample) %>%
    class_metrics(obs, estimate = pred)

# If you need to set options for certain metrics,
# do so by wrapping the metric and setting the options inside the wrapper,
# passing along truth and estimate as quoted arguments.
# Then add on the function class of the underlying wrapped function,
# and the direction of optimization.
ccc_with_bias <- function(data, truth, estimate, na_rm = TRUE, ...) {
    ccc(
        data = data,
        truth = !! rlang::enquo(truth),

**metric_summarizer**

*Developer function for summarizing new metrics*

**Description**

`metric_summarizer()` is useful alongside `metric_vec_template()` for implementing new custom metrics. `metric_summarizer()` calls the metric function inside `dplyr::summarise()`. `metric_vec_template()` is a generalized function that calls the core implementation of a metric function, and includes a number of checks on the types, lengths, and argument inputs. See vignette("custom-metrics","yardstick") for more information.

**Usage**

```
metric_summarizer(
  metric_nm,  
  metric_fn,  
  data,  
  truth,  
  estimate,  
  estimator = NULL,  
  na_rm = TRUE,  
)  
```
event_level = NULL,
...,
metric_fn_options = list()}

Arguments

metric_nm
A single character representing the name of the metric to use in the tibble output. This will be modified to include the type of averaging if appropriate.

metric_fn
The vector version of your custom metric function. It generally takes truth, estimate, na_rm, and any other extra arguments needed to calculate the metric.

data
The data frame with truth and estimate columns passed in from the data frame version of your metric function that called metric_summarizer().

truth
The unquoted column name corresponding to the truth column.

estimate
Generally, the unquoted column name corresponding to the estimate column. For metrics that take multiple columns through ... like class probability metrics, this is a result of dots_to_estimate().

estimator
For numeric metrics, this is left as NULL so averaging is not passed on to the metric function implementation. For classification metrics, this can either be NULL for the default auto-selection of averaging ("binary" or "macro"), or a single character to pass along to the metric implementation describing the kind of averaging to use.

na_rm
A logical value indicating whether NA values should be stripped before the computation proceeds. The removal is executed in metric_vec_template().

event_level
For numeric metrics, this is left as NULL to prevent it from being passed on to the metric function implementation. For classification metrics, this can either be NULL to use the default event_level value of the metric_fn or a single string of either "first" or "second" to pass along describing which level should be considered the "event".

...
Currently not used. Metric specific options are passed in through metric_fn_options.

metric_fn_options
A named list of metric specific options. These are spliced into the metric function call using !!! from rlang. The default results in nothing being spliced into the call.

Details

metric_summarizer() is generally called from the data frame version of your metric function. It knows how to call your metric over grouped data frames and returns a tibble consistent with other metrics.

metric_vec_template() finalize_estimator() dots_to_estimate()
\section*{metric_tweak \hfill Tweak a metric function}

\subsection*{Description}
metric_tweak() allows you to tweak an existing metric .fn, giving it a new .name and setting new optional argument defaults through \ldots. It is similar to purrr::partial(), but is designed specifically for yardstick metrics.

metric_tweak() is especially useful when constructing a \texttt{metric_set()} for tuning with the tune package. After the metric set has been constructed, there is no way to adjust the value of any optional arguments (such as beta in \texttt{f_meas()}). Using metric_tweak(), you can set optional arguments to custom values ahead of time, before they go into the metric set.

\subsection*{Usage}
\begin{verbatim}
metric_tweak(.name, .fn, ...)
\end{verbatim}

\subsection*{Arguments}
- \texttt{.name} \quad A single string giving the name of the new metric. This will be used in the ".metric" column of the output.
- \texttt{.fn} \quad An existing yardstick metric function to tweak.
- \ldots \quad Name-value pairs specifying which optional arguments to override and the values to replace them with.
  
  Arguments data, truth, and estimate are considered \textit{protected}, and cannot be overridden, but all other optional arguments can be altered.

\subsection*{Details}
The function returned from metric_tweak() only takes \ldots as arguments, which are passed through to the original .fn. Passing data, truth, and estimate through by position should generally be safe, but it is recommended to pass any other optional arguments through by name to ensure that they are evaluated correctly.

\subsection*{Value}
A tweaked version of .fn, updated to use new defaults supplied in \ldots.

\subsection*{Examples}
\begin{verbatim}
mase12 <- metric_tweak("mase12", mase, m = 12)

# Defaults to \texttt{`m = 1`}  
mase(solubility_test, solubility, prediction)

# Updated to use \texttt{`m = 12`}. \texttt{`mase12()`} has this set already.  
mase(solubility_test, solubility, prediction, m = 12)
\end{verbatim}
```r
mase12(solubility_test, solubility, prediction)

# This is most useful to set optional argument values ahead of time when
# using a metric_set
mase10 <- metric_tweak("mase10", mase, m = 10)
metrics <- metric_set(mase, mase10, mase12)
metrics(solubility_test, solubility, prediction)
```

---

**metric_vec_template**  
*Developer function for calling new metrics*

**Description**

`metric_vec_template()` is useful alongside `metric_summarizer()` for implementing new custom metrics. `metric_summarizer()` calls the metric function inside `dplyr::summarise()`. `metric_vec_template()` is a generalized function that calls the core implementation of a metric function, and includes a number of checks on the types, lengths, and argument inputs.

**Usage**

```r
metric_vec_template(
  metric_impl,
  truth,
  estimate,
  na_rm = TRUE,
  cls = "numeric",
  estimator = NULL,
  ...
)
```

**Arguments**

- `metric_impl`  
The core implementation function of your custom metric. This core implementation function is generally defined inside the vector method of your metric function.

- `truth`  
The realized vector of truth. This is either a factor or a numeric.

- `estimate`  
The realized estimate result. This is either a numeric vector, a factor vector, or a numeric matrix (in the case of multiple class probability columns) depending on your metric function.

- `na_rm`  
A logical value indicating whether NA values should be stripped before the computation proceeds. NA values are removed before getting to your core implementation function so you do not have to worry about handling them yourself. If `na_rm=FALSE` and any NA values exist, then NA is automatically returned.

- `cls`  
A character vector of length 1 or 2 corresponding to the class that `truth` and `estimate` should be, respectively. If `truth` and `estimate` are of the same class, just supply a vector of length 1. If they are different, supply a vector of length 2. For matrices, it is best to supply "numeric" as the class to check here.
estimator

The type of averaging to use. By this point, the averaging type should be finalized, so this should be a character vector of length 1. By default, this character value is required to be one of: "binary", "macro", "micro", or "macro_weighted". If your metric allows more or less averaging methods, override this with averaging_override.

Extra arguments to your core metric function, metric_impl, can technically be passed here, but generally the extra args are added through R's scoping rules because the core metric function is created on the fly when the vector method is called.

Details

dotscastbl() is called from the vector implementation of your metric. Also defined inside your vector implementation is a separate function performing the core implementation of the metric function. This core function is passed along to metric_vec_template() as metric_impl.

metric_summarizer() finalize_estimator() dots_to_estimate()

mn_log_loss

Mean log loss for multinomial data

Description

Compute the logarithmic loss of a classification model.

Usage

mn_log_loss(data, ...)

## S3 method for class 'data.frame'
mn_log_loss(
  data,
  truth,
  ...,
  na.rm = TRUE,
  sum = FALSE,
  event_level = yardstick_event_level()
)

mn_log_loss_vec(
  truth,
  estimate,
  na.rm = TRUE,
  sum = FALSE,
  event_level = yardstick_event_level(),
  ...
)
Arguments

- **data**: A `data.frame` containing the truth and estimate columns.

- **...**: A set of unquoted column names or one or more `dplyr` selector functions to choose which variables contain the class probabilities. If truth is binary, only 1 column should be selected. Otherwise, there should be as many columns as factor levels of truth.

- **truth**: The column identifier for the true class results (that is a factor). This should be an unquoted column name although this argument is passed by expression and supports quasiquotation (you can unquote column names). For `_vec()` functions, a factor vector.

- **na.rm**: A logical value indicating whether NA values should be stripped before the computation proceeds.

- **sum**: A logical. Should the sum of the likelihood contributions be returned (instead of the mean value)?

- **event_level**: A single string. Either "first" or "second" to specify which level of truth to consider as the "event". This argument is only applicable when `estimator = "binary"`. The default uses an internal helper that generally defaults to "first", however, if the deprecated global option `yardstick.event_first` is set, that will be used instead with a warning.

- **estimate**: If truth is binary, a numeric vector of class probabilities corresponding to the "relevant" class. Otherwise, a matrix with as many columns as factor levels of truth. It is assumed that these are in the same order as the levels of truth.

Details

Log loss is a measure of the performance of a classification model. A perfect model has a log loss of 0.

Compared with `accuracy()`, log loss takes into account the uncertainty in the prediction and gives a more detailed view into the actual performance. For example, given two input probabilities of .6 and .9 where both are classified as predicting a positive value, say, "Yes", the accuracy metric would interpret them as having the same value. If the true output is "Yes", log loss penalizes .6 because it is "less sure" of its result compared to the probability of .9.

Value

- A tibble with columns `.metric`, `.estimator`, and `.estimate` and 1 row of values.

  For grouped data frames, the number of rows returned will be the same as the number of groups.

  For `mn_log_loss_vec()`, a single numeric value (or NA).

Multiclass

Log loss has a known multiclass extension, and is simply the sum of the log loss values for each class prediction. Because of this, no averaging types are supported.

# Groups are respected
hpc_cv %>%
  group_by(Resample) %>%
mn_log_loss(obs, VF:L)

# Vector version
# Supply a matrix of class probabilities
fold1 <- hpc_cv %>%
  filter(Resample == "Fold01")

mn_log_loss_vec(
  truth = fold1$obs,
  matrix(
    c(fold1$VF, fold1$F, fold1$M, fold1$L),
    ncol = 4
  )
)

# Supply `...` with quasiquotation
prob_cols <- levels(two_class_example$truth)
mn_log_loss(two_class_example, truth, Class1)
mn_log_loss(two_class_example, truth, !! prob_cols[1])
```

---

**mpe**  
*Mean percentage error*
Description

Calculate the mean percentage error. This metric is in relative units. It can be used as a measure of the estimate’s bias.

Note that if any truth values are 0, a value of: -Inf (estimate > 0), Inf (estimate < 0), or NaN (estimate == 0) is returned for mpe().

Usage

mpe(data, ...)

## S3 method for class 'data.frame'
mpe(data, truth, estimate, na_rm = TRUE, ...)

mpe_vec(truth, estimate, na_rm = TRUE, ...)

Arguments

data       A data.frame containing the truth and estimate columns.
...        Not currently used.
truth      The column identifier for the true results (that is numeric). This should be an unquoted column name although this argument is passed by expression and supports quasiquotation (you can unquote column names). For _vec() functions, a numeric vector.
estimate   The column identifier for the predicted results (that is also numeric). As with truth this can be specified different ways but the primary method is to use an unquoted variable name. For _vec() functions, a numeric vector.
na_rm       A logical value indicating whether NA values should be stripped before the computation proceeds.

Value

A tibble with columns .metric, .estimator, and .estimate and 1 row of values.
For grouped data frames, the number of rows returned will be the same as the number of groups.
For mpe_vec(), a single numeric value (or NA).

Examples

```r
# `solubility_test$solubility` has zero values with corresponding # `prediction` values that are negative. By definition, this causes `Inf` # to be returned from `mpe()`. solubility_test[solubility_test$solubility == 0,]

mpe(solubility_test, solubility, prediction)

# We'll remove the zero values for demonstration solubility_test <- solubility_test[solubility_test$solubility != 0,]

# Supply truth and predictions as bare column names mpe(solubility_test, solubility, prediction)

library(dplyr)

set.seed(1234)
size <- 100
times <- 10

# create 10 resamples solubility_resampled <- bind_rows(
  replicate(
    n = times,
    expr = sample_n(solubility_test, size, replace = TRUE),
    simplify = FALSE
  ),
  .id = "resample"
)

# Compute the metric by group metric_results <- solubility_resampled %>%
  group_by(resample) %>%
  mpe(solubility, prediction)

metric_results

# Resampled mean estimate metric_results %>%
  summarise(avg_estimate = mean(.estimate))
```

---

**msd**

*Mean signed deviation*

**Description**

Mean signed deviation (also known as mean signed difference, or mean signed error) computes the average differences between truth and estimate. A related metric is the mean absolute error (`mae()`).
Usage

msd(data, ...)

## S3 method for class 'data.frame'
msd(data, truth, estimate, na_rm = TRUE, ...)

msd_vec(truth, estimate, na_rm = TRUE, ...)

Arguments

data

A data.frame containing the truth and estimate columns.

...  

Not currently used.

truth

The column identifier for the true results (that is numeric). This should be an unquoted column name although this argument is passed by expression and supports quasiquotation (you can unquote column names). For _vec() functions, a numeric vector.

estimate

The column identifier for the predicted results (that is also numeric). As with truth this can be specified different ways but the primary method is to use an unquoted variable name. For _vec() functions, a numeric vector.

na_rm

A logical value indicating whether NA values should be stripped before the computation proceeds.

Details

Mean signed deviation is rarely used, since positive and negative errors cancel each other out. For example, msd_vec(c(100,-100),c(0,0)) would return a seemingly "perfect" value of 0, even though estimate is wildly different from truth. mae() attempts to remedy this by taking the absolute value of the differences before computing the mean.

This metric is computed as \(\text{mean}(\text{truth} - \text{estimate})\), following the convention that an "error" is computed as observed - predicted. If you expected this metric to be computed as \(\text{mean}(\text{estimate} - \text{truth})\), reverse the sign of the result.

Value

A tibble with columns .metric, .estimator, and .estimate and 1 row of values.

For grouped data frames, the number of rows returned will be the same as the number of groups.

For msd_vec(), a single numeric value (or NA).

### new-metric

**Construct a new metric function**

### Description

These functions provide convenient wrappers to create the three types of metric functions in yardstick: numeric metrics, class metrics, and class probability metrics. They add a metric-specific class to fn and attach a direction attribute. These features are used by `metric_set()` and by `tune` when model tuning.

See vignette("custom-metrics") for more information about creating custom metrics.

### Usage

`new_class_metric(fn, direction)`

`new_prob_metric(fn, direction)`

`new_numeric_metric(fn, direction)`
Arguments

fn  A function. The metric function to attach a metric-specific class and direction attribute to.

direction  A string. One of:
- "maximize"
- "minimize"
- "zero"

---

npv  Negative predictive value

Description

These functions calculate the npv() (negative predictive value) of a measurement system compared to a reference result (the "truth" or gold standard). Highly related functions are spec(), sens(), andppv().

Usage

npv(data, ...)

## S3 method for class 'data.frame'
npv(
  data,  
  truth,  
  estimate,  
  prevalence = NULL,  
  estimator = NULL,  
  na.rm = TRUE,  
  event_level = yardstick_event_level(),  
  ...
)

npv_vec(
  truth,  
  estimate,  
  prevalence = NULL,  
  estimator = NULL,  
  na.rm = TRUE,  
  event_level = yardstick_event_level(),  
  ...
)
Arguments

- **data**: Either a `data.frame` containing the truth and estimate columns, or a table/matrix where the true class results should be in the columns of the table.
- **truth**: The column identifier for the true class results (that is a `factor`). This should be an unquoted column name although this argument is passed by expression and supports quasiquote (you can unquote column names). For `.vec()` functions, a `factor` vector.
- **estimate**: The column identifier for the predicted class results (that is also `factor`). As with truth this can be specified different ways but the primary method is to use an unquoted variable name. For `.vec()` functions, a `factor` vector.
- **prevalence**: A numeric value for the rate of the "positive" class of the data.
- **estimator**: One of: "binary", "macro", "macro_weighted", or "micro" to specify the type of averaging to be done. "binary" is only relevant for the two class case. The other three are general methods for calculating multiclass metrics. The default will automatically choose "binary" or "macro" based on estimator.
- **na_rm**: A logical value indicating whether NA values should be stripped before the computation proceeds.
- **event_level**: A single string. Either "first" or "second" to specify which level of truth to consider as the "event". This argument is only applicable when estimator = "binary". The default uses an internal helper that generally defaults to "first", however, if the deprecated global option `yardstick.event_first` is set, that will be used instead with a warning.

Details

The positive predictive value (`ppv()`) is defined as the percent of predicted positives that are actually positive while the negative predictive value (`npv()`) is defined as the percent of negative positives that are actually negative.

Value

A tibble with columns `.metric`, `.estimator`, and `.estimate` and 1 row of values.

For grouped data frames, the number of rows returned will be the same as the number of groups.

For `npv_vec()`, a single numeric value (or NA).

Relevant Level

There is no common convention on which factor level should automatically be considered the "event" or "positive" result when computing binary classification metrics. In `yardstick`, the default is to use the first level. To alter this, change the argument event_level to "second" to consider the last level of the factor the level of interest. For multiclass extensions involving one-vs-all comparisons (such as macro averaging), this option is ignored and the "one" level is always the relevant result.
**Multiclass**

Macro, micro, and macro-weighted averaging is available for this metric. The default is to select macro averaging if a truth factor with more than 2 levels is provided. Otherwise, a standard binary calculation is done. See vignette("multiclass","yardstick") for more information.

**Implementation**

Suppose a 2x2 table with notation:

<table>
<thead>
<tr>
<th>Reference</th>
<th>Predicted</th>
<th>Positive</th>
<th>Negative</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Positive</td>
<td>A</td>
<td>B</td>
</tr>
<tr>
<td></td>
<td>Negative</td>
<td>C</td>
<td>D</td>
</tr>
</tbody>
</table>

The formulas used here are:

\[
\text{Sensitivity} = \frac{A}{A + C}
\]

\[
\text{Specificity} = \frac{D}{B + D}
\]

\[
\text{Prevalence} = \frac{A + C}{A + B + C + D}
\]

\[
PPV = \frac{(\text{Sensitivity} \times \text{Prevalence})}{((\text{Sensitivity} \times \text{Prevalence}) + ((1 - \text{Specificity}) \times (1 - \text{Prevalence})))}
\]

\[
NPV = \frac{(\text{Specificity} \times (1 - \text{Prevalence}))}{(((1 - \text{Sensitivity}) \times \text{Prevalence}) + ((\text{Specificity} \times (1 - \text{Prevalence})))}
\]

See the references for discussions of the statistics.

poisson_log_loss  *Mean log loss for Poisson data*

Description

Calculate the loss function for the Poisson distribution.

Usage

poisson_log_loss(data, ...)

## S3 method for class 'data.frame'
poisson_log_loss(data, truth, estimate, na_rm = TRUE, ...)

poisson_log_loss_vec(truth, estimate, na_rm = TRUE, ...)

Arguments

- **data**
  A *data.frame* containing the truth and estimate columns.
- **...**
  Not currently used.
- **truth**
  The column identifier for the true counts (that is integer). This should be an unquoted column name although this argument is passed by expression and supports *quasiquotation* (you can unquote column names). For _vec() functions, an integer vector.
- **estimate**
  The column identifier for the predicted results (that is also numeric). As with truth this can be specified different ways but the primary method is to use an unquoted variable name. For _vec() functions, a numeric vector.
- **na_rm**
  A logical value indicating whether NA values should be stripped before the computation proceeds.
**Value**

A tibble with columns `metric`, `estimator`, and `estimate` and 1 row of values.

For grouped data frames, the number of rows returned will be the same as the number of groups.

For `poisson_log_loss_vec()`, a single numeric value (or NA).

Other accuracy metrics: `ccc()`, `huber_loss_pseudo()`, `huber_loss()`, `iic()`, `mae()`, `mape()`, `mase()`, `mpe()`, `msd()`, `rmse()`, `smape()`

**Examples**

```r
count_truth <- c(2L, 7L, 1L, 1L, 0L, 3L)
count_pred <- c(2.14, 5.35, 1.65, 1.56, 1.3, 2.71)
count_results <- dplyr::tibble(count = count_truth, pred = count_pred)

# Supply truth and predictions as bare column names
poisson_log_loss(count_results, count, pred)
```

---

**Description**

These functions calculate the `ppv()` (positive predictive value) of a measurement system compared to a reference result (the "truth" or gold standard). Highly related functions are `spec()`, `sens()`, and `npv()`.

**Usage**

```r
ppv(data, ...)
```

## S3 method for class 'data.frame'

```r
ppv(
  data,
  truth,
  estimate,
  prevalence = NULL,
  estimator = NULL,
  na_rm = TRUE,
)```
event_level = yardstick_event_level(),
...
)

ppv_vec(
  truth,
  estimate,
  prevalence = NULL,
  estimator = NULL,
  na_rm = TRUE,
  event_level = yardstick_event_level(),
  ...
)

Arguments

data
  Either a \texttt{data.frame} containing the \texttt{truth} and \texttt{estimate} columns, or a \texttt{table/matrix} where the true class results should be in the columns of the table.

... 
  Not currently used.

truth
  The column identifier for the true class results (that is a \texttt{factor}). This should be an unquoted column name although this argument is passed by expression and supports \texttt{quasiquotation} (you can unquote column names). For \texttt{vec()} functions, a \texttt{factor} vector.

estimate
  The column identifier for the predicted class results (that is also \texttt{factor}). As with \texttt{truth} this can be specified different ways but the primary method is to use an unquoted variable name. For \texttt{vec()} functions, a \texttt{factor} vector.

prevalence
  A numeric value for the rate of the "positive" class of the data.

estimator
  One of: "binary", "macro", "macro_weighted", or "micro" to specify the type of averaging to be done. "binary" is only relevant for the two class case. The other three are general methods for calculating multiclass metrics. The default will automatically choose "binary" or "macro" based on \texttt{estimate}.

na_rm
  A logical value indicating whether NA values should be stripped before the computation proceeds.

event_level
  A single string. Either "first" or "second" to specify which level of \texttt{truth} to consider as the "event". This argument is only applicable when \texttt{estimator = "binary"}. The default uses an internal helper that generally defaults to "first", however, if the deprecated global option \texttt{yardstick.event_first} is set, that will be used instead with a warning.

Details

The positive predictive value (\texttt{ppv()}) is defined as the percent of predicted positives that are actually positive while the negative predictive value (\texttt{npv()}) is defined as the percent of negative positives that are actually negative.
ppv

Value
A tibble with columns .metric, .estimator, and .estimate and 1 row of values.
For grouped data frames, the number of rows returned will be the same as the number of groups.
For ppv_vec(), a single numeric value (or NA).

Relevant Level
There is no common convention on which factor level should automatically be considered the
"event" or "positive" result when computing binary classification metrics. In yardstick, the default
is to use the first level. To alter this, change the argument event_level to "second" to consider
the last level of the factor the level of interest. For multiclass extensions involving one-vs-all com-
parisons (such as macro averaging), this option is ignored and the "one" level is always the relevant
result.

Multiclass
Macro, micro, and macro-weighted averaging is available for this metric. The default is to select
macro averaging if a truth factor with more than 2 levels is provided. Otherwise, a standard binary
calculation is done. See vignette("multiclass", "yardstick") for more information.

Implementation
Suppose a 2x2 table with notation:

<table>
<thead>
<tr>
<th>Predicted</th>
<th>Reference</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Positive</td>
<td>Positive</td>
<td>A</td>
</tr>
<tr>
<td>Negative</td>
<td>Negative</td>
<td>C</td>
</tr>
</tbody>
</table>

The formulas used here are:

$$Sensitivity = \frac{A}{A + C}$$

$$Specificity = \frac{D}{B + D}$$

$$Prevalence = \frac{A + C}{A + B + C + D}$$

$$PPV = \frac{(Sensitivity \times Prevalence)}{((Sensitivity \times Prevalence) + ((1 - Specificity) \times (1 - Prevalence)))}$$

$$NPV = \frac{(Specificity \times (1 - Prevalence))}{(((1 - Sensitivity) \times Prevalence) + ((Specificity) \times (1 - Prevalence)))}$$

See the references for discussions of the statistics.

# Vector version
ppv_vec(
  two_class_example$truth,
  two_class_example$predicted
)

# Making Class2 the "relevant" level
ppv_vec(
  two_class_example$truth,
  two_class_example$predicted,
  event_level = "second"
)

# But what if we think that Class 1 only occurs 40% of the time?
ppv(two_class_example, truth, predicted, prevalence = 0.40)
```
**Description**

These functions calculate the **precision()** of a measurement system for finding relevant documents compared to reference results (the truth regarding relevance). Highly related functions are **recall()** and **f_meas()**.

**Usage**

```r
precision(data, ...)
```

```r
## S3 method for class 'data.frame'
precision(
  data,
  truth,
  estimate,
  estimator = NULL,
  na_rm = TRUE,
  event_level = yardstick_event_level(),
  ...
)
```

```r
precision_vec(
  truth,
  estimate,
  estimator = NULL,
  na_rm = TRUE,
  event_level = yardstick_event_level(),
  ...
)
```

**Arguments**

- **data**
  - Either a `data.frame` containing the `truth` and `estimate` columns, or a `table/matrix` where the true class results should be in the columns of the table.
- **...**
  - Not currently used.
- **truth**
  - The column identifier for the true class results (that is a `factor`). This should be an unquoted column name although this argument is passed by expression and supports `quasiquotation` (you can unquote column names). For `_vec()` functions, a `factor` vector.
- **estimate**
  - The column identifier for the predicted class results (that is also `factor`). As with `truth` this can be specified different ways but the primary method is to use an unquoted variable name. For `_vec()` functions, a `factor` vector.
estimator

One of: "binary", "macro", "macro_weighted", or "micro" to specify the type of averaging to be done. "binary" is only relevant for the two class case. The other three are general methods for calculating multiclass metrics. The default will automatically choose "binary" or "macro" based on estimate.

na_rm

A logical value indicating whether NA values should be stripped before the computation proceeds.

event_level

A single string. Either "first" or "second" to specify which level of truth to consider as the "event". This argument is only applicable when estimator = "binary". The default uses an internal helper that generally defaults to "first", however, if the deprecated global option yardstick.event_first is set, that will be used instead with a warning.

Details

The precision is the percentage of predicted truly relevant results of the total number of predicted relevant results and characterizes the "purity in retrieval performance" (Buckland and Gey, 1994).

When the denominator of the calculation is 0, precision is undefined. This happens when both # true_positive = 0 and # false_positive = 0 are true, which mean that there were no predicted events. When computing binary precision, a NA value will be returned with a warning. When computing multiclass precision, the individual NA values will be removed, and the computation will proceed, with a warning.

Value

A tibble with columns .metric, .estimator, and .estimate and 1 row of values.

For grouped data frames, the number of rows returned will be the same as the number of groups.

For precision_vec(), a single numeric value (or NA).

Relevant Level

There is no common convention on which factor level should automatically be considered the "event" or "positive" result when computing binary classification metrics. In yardstick, the default is to use the first level. To alter this, change the argument event_level to "second" to consider the last level of the factor the level of interest. For multiclass extensions involving one-vs-all comparisons (such as macro averaging), this option is ignored and the "one" level is always the relevant result.

Multiclass

Macro, micro, and macro-weighted averaging is available for this metric. The default is to select macro averaging if a truth factor with more than 2 levels is provided. Otherwise, a standard binary calculation is done. See vignette("multiclass","yardstick") for more information.

Implementation

Suppose a 2x2 table with notation:

Reference
The formulas used here are:

\[
\text{recall} = \frac{A}{(A + C)}
\]

\[
\text{precision} = \frac{A}{(A + B)}
\]

\[
F_{\text{meas}} = \frac{(1 + \beta^2) \cdot \text{precision} \cdot \text{recall}}{(\beta^2 \cdot \text{precision}) + \text{recall}}
\]

See the references for discussions of the statistics.

pr_auc

Area under the precision recall curve

Description

pr_auc() is a metric that computes the area under the precision recall curve. See pr_curve() for the full curve.

Usage

pr_auc(data, ...)

## S3 method for class 'data.frame'
pr_auc(
  data,
  truth,
  ..., 
  estimator = NULL,
  na.rm = TRUE,
  event_level = yardstick_event_level()
)

pr_auc_vec(
  truth,
  estimate,
  estimator = NULL,
  na.rm = TRUE,
  event_level = yardstick_event_level(),
  ...
)
Arguments

data A data.frame containing the truth and estimate columns.

... A set of unquoted column names or one or more dplyr selector functions to choose which variables contain the class probabilities. If truth is binary, only 1 column should be selected. Otherwise, there should be as many columns as factor levels of truth.

truth The column identifier for the true class results (that is a factor). This should be an unquoted column name although this argument is passed by expression and supports quasiquotation (you can unquote column names). For vec() functions, a factor vector.

estimator One of "binary", "macro", or "macro_weighted" to specify the type of averaging to be done. "binary" is only relevant for the two class case. The other two are general methods for calculating multiclass metrics. The default will automatically choose "binary" or "macro" based on truth.

na_rm A logical value indicating whether NA values should be stripped before the computation proceeds.

event_level A single string. Either "first" or "second" to specify which level of truth to consider as the "event". This argument is only applicable when estimator = "binary". The default uses an internal helper that generally defaults to "first", however, if the deprecated global option yardstick.event_first is set, that will be used instead with a warning.

estimate If truth is binary, a numeric vector of class probabilities corresponding to the "relevant" class. Otherwise, a matrix with as many columns as factor levels of truth. It is assumed that these are in the same order as the levels of truth.

Value

A tibble with columns .metric, .estimator, and .estimate and 1 row of values.

For grouped data frames, the number of rows returned will be the same as the number of groups.

For pr_auc_vec(), a single numeric value (or NA).

Multiclass

Macro and macro-weighted averaging is available for this metric. The default is to select macro averaging if a truth factor with more than 2 levels is provided. Otherwise, a standard binary calculation is done. See vignette("multiclass","yardstick") for more information.

Relevant Level

There is no common convention on which factor level should automatically be considered the "event" or "positive" result when computing binary classification metrics. In yardstick, the default is to use the first level. To alter this, change the argument event_level to "second" to consider the last level of the factor the level of interest. For multiclass extensions involving one-vs-all comparisons (such as macro averaging), this option is ignored and the "one" level is always the relevant result.

Examples

# Two class example

# `truth` is a 2 level factor. The first level is `"Class1"`, which is the
# "event of interest" by default in yardstick. See the Relevant Level
# section above.
# Binary metrics using class probabilities take a factor `truth` column,
# and a single class probability column containing the probabilities of
# the event of interest. Here, since `"Class1"` is the first level of
# `"truth"`, it is the event of interest and we pass in probabilities for it.
# `pr_auc(two_class_example, truth, Class1)`

# Multiclass example

# `obs` is a 4 level factor. The first level is `"VF"`, which is the
# "event of interest" by default in yardstick. See the Relevant Level
# section above.
# You can use the col1:colN tidyselect syntax
# `pr_auc(two_class_example, truth, Class1)`

# Change the first level of `obs` from `"VF"` to `"M"` to alter the
# event of interest. The class probability columns should be supplied
# in the same order as the levels.
# `pr_auc(two_class_example, truth, Class1)`

# Groups are respected
# Weighted macro averaging
hpc_cv %>%
  group_by(Resample) %>%
  pr_auc(obs, VF:L, estimator = "macro_weighted")

# Vector version
# Supply a matrix of class probabilities
fold1 <- hpc_cv %>%
  filter(Resample == "Fold01")

pr_auc_vec(
  truth = fold1$obs,
  matrix(
    c(fold1$VF, fold1$F, fold1$M, fold1$L),
    ncol = 4
  )
)

---

**pr_curve**

**Precision recall curve**

**Description**

`pr_curve()` constructs the full precision recall curve and returns a tibble. See `pr_auc()` for the area under the precision recall curve.

**Usage**

```r
pr_curve(data, ...)```

## S3 method for class 'data.frame'
```r
pr_curve(data, truth, ..., na_rm = TRUE, event_level = yardstick_event_level())```

**Arguments**

- **data** A data.frame containing the truth and estimate columns.
- **...** A set of unquoted column names or one or more dplyr selector functions to choose which variables contain the class probabilities. If truth is binary, only 1 column should be selected. Otherwise, there should be as many columns as factor levels of truth.
- **truth** The column identifier for the true class results (that is a factor). This should be an unquoted column name although this argument is passed by expression and supports quasiquotation (you can unquote column names). For _vec() functions, a factor vector.
- **na_rm** A logical value indicating whether NA values should be stripped before the computation proceeds.
**event_level**

A single string. Either "first" or "second" to specify which level of truth to consider as the "event". This argument is only applicable when estimator = "binary". The default uses an internal helper that generally defaults to "first", however, if the deprecated global option yardstick.event_first is set, that will be used instead with a warning.

**Details**

`pr_curve()` computes the precision at every unique value of the probability column (in addition to infinity).

There is a `ggplot2::autoplot()` method for quickly visualizing the curve. This works for binary and multiclass output, and also works with grouped data (i.e. from resamples). See the examples.

**Value**

A tibble with class `pr_df` or `pr_grouped_df` having columns `.threshold`, `.recall`, and `.precision`.

**Multiclass**

If a multiclass truth column is provided, a one-vs-all approach will be taken to calculate multiple curves, one per level. In this case, there will be an additional column, `.level`, identifying the "one" column in the one-vs-all calculation.

**Relevant Level**

There is no common convention on which factor level should automatically be considered the "event" or "positive" result when computing binary classification metrics. In yardstick, the default is to use the first level. To alter this, change the argument `event_level` to "second" to consider the last level of the factor the level of interest. For multiclass extensions involving one-vs-all comparisons (such as macro averaging), this option is ignored and the "one" level is always the relevant result.

**Author(s)**

Max Kuhn

**See Also**

Compute the area under the precision recall curve with `pr_auc()`.

Other curve metrics: `gain_curve()`, `lift_curve()`, `roc_curve()`

**Examples**

```r
# Two class example

data(two_class_example)
```

# `truth` is a 2 level factor. The first level is "Class1", which is the
# "event of interest" by default in yardstick. See the Relevant Level
# section above.

data(two_class_example)
Recall

Description

These functions calculate the recall() of a measurement system for finding relevant documents compared to reference results (the truth regarding relevance). Highly related functions are precision() and f_meas().

Usage

recall(data, ...)

## S3 method for class 'data.frame'
recall(
  data,
  truth,
  estimate,
  estimator = NULL,
  na_rm = TRUE,
  event_level = yardstick_event_level(),
  ...
)

recall_vec(
  truth,
  estimate,
  estimator = NULL,
  na_rm = TRUE,
  event_level = yardstick_event_level(),
  ...
)

Arguments

data Either a data.frame containing the truth and estimate columns, or a table/matrix where the true class results should be in the columns of the table.

... Not currently used.

truth The column identifier for the true class results (that is a factor). This should be an unquoted column name although this argument is passed by expression and supports quasiquotation (you can unquote column names). For_vec() functions, a factor vector.

estimate The column identifier for the predicted class results (that is also factor). As with truth this can be specified different ways but the primary method is to use an unquoted variable name. For_vec() functions, a factor vector.

estimator One of: "binary", "macro", "macro_weighted", or "micro" to specify the type of averaging to be done. "binary" is only relevant for the two class case. The other three are general methods for calculating multiclass metrics. The default will automatically choose "binary" or "macro" based on estimate.

na_rm A logical value indicating whether NA values should be stripped before the computation proceeds.

event_level A single string. Either "first" or "second" to specify which level of truth to consider as the "event". This argument is only applicable when estimator = "binary". The default uses an internal helper that generally defaults to "first". However, if the deprecated global option yardstick.event_first is set, that will be used instead with a warning.

Details

The recall (aka sensitivity) is defined as the proportion of relevant results out of the number of samples which were actually relevant. When there are no relevant results, recall is not defined and a value of NA is returned.
When the denominator of the calculation is 0, recall is undefined. This happens when both \( \text{true_positive} = 0 \) and \( \text{false_negative} = 0 \) are true, which mean that there were no true events. When computing binary recall, a NA value will be returned with a warning. When computing multiclass recall, the individual NA values will be removed, and the computation will proceed, with a warning.

**Value**

A tibble with columns .metric, .estimator, and .estimate and 1 row of values.

For grouped data frames, the number of rows returned will be the same as the number of groups.

For \text{recall_vec()}, a single numeric value (or NA).

**Relevant Level**

There is no common convention on which factor level should automatically be considered the "event" or "positive" result when computing binary classification metrics. In yardstick, the default is to use the first level. To alter this, change the argument \text{event_level} to "second" to consider the last level of the factor the level of interest. For multiclass extensions involving one-vs-all comparisons (such as macro averaging), this option is ignored and the "one" level is always the relevant result.

**Multiclass**

Macro, micro, and macro-weighted averaging is available for this metric. The default is to select macro averaging if a truth factor with more than 2 levels is provided. Otherwise, a standard binary calculation is done. See vignette("multiclass","yardstick") for more information.

**Implementation**

Suppose a 2x2 table with notation:

| Predicted | Reference |  |
|-----------|-----------|  |
| Relevant  | A         | B |
| Irrelevant| C         | D |

The formulas used here are:

\[
\text{recall} = A/(A + C) \\
\text{precision} = A/(A + B) \\
F_{\text{meas}} = (1 + \beta^2) \ast \text{precision} \ast \text{recall}/((\beta^2 \ast \text{precision}) + \text{recall})
\]

See the references for discussions of the statistics.

rmse

Root mean squared error

Description

Calculate the root mean squared error. rmse() is a metric that is in the same units as the original data.

Usage

rmse(data, ...)

## S3 method for class 'data.frame'
rmse(data, truth, estimate, na_rm = TRUE, ...)

rmse_vec(truth, estimate, na_rm = TRUE, ...)

Arguments

data

A data.frame containing the truth and estimate columns.

...

Not currently used.

truth

The column identifier for the true results (that is numeric). This should be an unquoted column name although this argument is passed by expression and supports quasiquotation (you can unquote column names). For _vec() functions, a numeric vector.

estimate

The column identifier for the predicted results (that is also numeric). As with truth this can be specified different ways but the primary method is to use an unquoted variable name. For _vec() functions, a numeric vector.

na_rm

A logical value indicating whether NA values should be stripped before the computation proceeds.

Value

A tibble with columns .metric, .estimator, and .estimate and 1 row of values.

For grouped data frames, the number of rows returned will be the same as the number of groups.

For rmse_vec(), a single numeric value (or NA).

**roc_auc**

*Area under the receiver operator curve*

Description

roc_auc() is a metric that computes the area under the ROC curve. See roc_curve() for the full curve.

Usage

roc_auc(data, ...)

## S3 method for class 'data.frame'
roc_auc(
  data,
  truth,
  ..., 
  options = list(),
)
roc_aucVec

estimator = NULL,
na.rm = TRUE,
event_level = yardstick_event_level()
)

roc_auc_vec(
  truth,
estimate,
options = list(),
estimator = NULL,
na.rm = TRUE,
event_level = yardstick_event_level(),
...
)

Arguments

data A data.frame containing the truth and estimate columns.
...
A set of unquoted column names or one or more dplyr selector functions to choose which variables contain the class probabilities. If truth is binary, only 1 column should be selected. Otherwise, there should be as many columns as factor levels of truth.

truth The column identifier for the true class results (that is a factor). This should be an unquoted column name although this argument is passed by expression and supports quasiquotation (you can unquote column names). For _vec() functions, a factor vector.

options A list of named options to pass to pROC::roc() such as smooth. These options should not include response, predictor, levels, quiet, or direction.

estimator One of "binary", "hand_till", "macro", or "macro_weighted" to specify the type of averaging to be done. "binary" is only relevant for the two class case. The others are general methods for calculating multiclass metrics. The default will automatically choose "binary" or "hand_till" based on truth.

na.rm A logical value indicating whether NA values should be stripped before the computation proceeds.

event_level A single string. Either "first" or "second" to specify which level of truth to consider as the "event". This argument is only applicable when estimator = "binary". The default uses an internal helper that generally defaults to "first", however, if the deprecated global option yardstick.event_first is set, that will be used instead with a warning.

estimate If truth is binary, a numeric vector of class probabilities corresponding to the "relevant" class. Otherwise, a matrix with as many columns as factor levels of truth. It is assumed that these are in the same order as the levels of truth.

Details

The underlying direction option in pROC::roc() is forced to direction = "<". This computes the ROC curve assuming that the estimate values are the probability that the "event" occurred, which is what they are always assumed to be in yardstick.
Generally, an ROC AUC value is between 0.5 and 1, with 1 being a perfect prediction model. If your value is between 0 and 0.5, then this implies that you have meaningful information in your model, but it is being applied incorrectly because doing the opposite of what the model predicts would result in an AUC >0.5.

Value

A tibble with columns .metric, .estimator, and .estimate and 1 row of values. For grouped data frames, the number of rows returned will be the same as the number of groups. For roc_auc_vec(), a single numeric value (or NA).

Relevant Level

There is no common convention on which factor level should automatically be considered the "event" or "positive" result when computing binary classification metrics. In yardstick, the default is to use the first level. To alter this, change the argument event_level to "second" to consider the last level of the factor the level of interest. For multiclass extensions involving one-vs-all comparisons (such as macro averaging), this option is ignored and the "one" level is always the relevant result.

Multiclass

The default multiclass method for computing roc_auc() is to use the method from Hand, Till, (2001). Unlike macro-averaging, this method is insensitive to class distributions like the binary ROC AUC case. Additionally, while other multiclass techniques will return NA if any levels in truth occur zero times in the actual data, the Hand-Till method will simply ignore those levels in the averaging calculation, with a warning.

Macro and macro-weighted averaging are still provided, even though they are not the default. In fact, macro-weighted averaging corresponds to the same definition of multiclass AUC given by Provost and Domingos (2001).

    matrix(
        c(fold1$VF, fold1$F, fold1$M, fold1$L),
        ncol = 4
    )
)

# Options for \texttt{\textbackslash pROC::roc()}  
# Pass options via a named list and not through `\ldots\!'  
roc_auc(  
    two_class_example,  
    truth = truth,  
    Class1,  
    options = list(smooth = TRUE)
)

\begin{verbatim}
roc_aunp  Area under the ROC curve of each class against the rest, using the a priori class distribution
\end{verbatim}

\textbf{Description}  

\texttt{roc_aunp()}  is a multiclass metric that computes the area under the ROC curve of each class against the rest, using the a priori class distribution. This is equivalent to \texttt{roc_auc(estimator = "macro_weighted").}

\textbf{Usage}  

\begin{verbatim}
roc_aunp(data, ...)  
## S3 method for class 'data.frame'  
roc_aunp(data, truth, ..., options = list(), na_rm = TRUE)
roc_aunp_vec(truth, estimate, options = list(), na_rm = TRUE, ...)
\end{verbatim}

\textbf{Arguments}  

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>data</td>
<td>A \texttt{data.frame} containing the truth and estimate columns.</td>
</tr>
<tr>
<td>...</td>
<td>A set of unquoted column names or one or more \texttt{dplyr} selector functions to choose which variables contain the class probabilities. There should be as many columns as factor levels of truth.</td>
</tr>
<tr>
<td>truth</td>
<td>The column identifier for the true class results (that is a \texttt{factor}). This should be an unquoted column name although this argument is passed by expression and supports \texttt{quasiquotation} (you can unquote column names). For _vec() functions, a \texttt{factor} vector.</td>
</tr>
</tbody>
</table>
options   A list of named options to pass to `pROC::roc()` such as smooth. These options should not include `response`, `predictor`, `levels`, `quiet`, or `direction`.

na_rm     A logical value indicating whether NA values should be stripped before the computation proceeds.

estimate  A matrix with as many columns as factor levels of truth. *It is assumed that these are in the same order as the levels of truth.*

Value

A tibble with columns `.metric`, `estimator`, and `estimate` and 1 row of values.

For grouped data frames, the number of rows returned will be the same as the number of groups.

For `roc_aunp_vec()`, a single numeric value (or NA).

Relevant Level

There is no common convention on which factor level should automatically be considered the "event" or "positive" result when computing binary classification metrics. In `yardstick`, the default is to use the first level. To alter this, change the argument `event_level` to "second" to consider the last level of the factor the level of interest. For multiclass extensions involving one-vs-all comparisons (such as macro averaging), this option is ignored and the "one" level is always the relevant result.

Multiclass

This multiclass method for computing the area under the ROC curve uses the a priori class distribution and is equivalent to `roc_auc(estimator = "macro_weighted")`.

roc_aunu

Area under the ROC curve of each class against the rest, using the uniform class distribution

Description

roc_aunu() is a multiclass metric that computes the area under the ROC curve of each class against the rest, using the uniform class distribution. This is equivalent to roc_auc(estimator = "macro").

Usage

roc_aunu(data, ...)

## S3 method for class 'data.frame'
roc_aunu(data, truth, ..., options = list(), na_rm = TRUE)

roc_aunu_vec(truth, estimate, options = list(), na_rm = TRUE, ...)

Arguments

data A data.frame containing the truth and estimate columns.
...
A set of unquoted column names or one or more dplyr selector functions to choose which variables contain the class probabilities. There should be as many columns as factor levels of truth.

truth The column identifier for the true class results (that is a factor). This should be an unquoted column name although this argument is passed by expression and supports quasiquotation (you can unquote column names). For _vec() functions, a factor vector.

options A list of named options to pass to pROC::roc() such as smooth. These options should not include response, predictor, levels, quiet, or direction.

na_rm A logical value indicating whether NA values should be stripped before the computation proceeds.

estimate A matrix with as many columns as factor levels of truth. It is assumed that these are in the same order as the levels of truth.

Value

A tibble with columns .metric, .estimator, and .estimate and 1 row of values.
For grouped data frames, the number of rows returned will be the same as the number of groups.
For roc_aunu_vec(), a single numeric value (or NA).
Relevant Level

There is no common convention on which factor level should automatically be considered the "event" or "positive" result when computing binary classification metrics. In yardstick, the default is to use the first level. To alter this, change the argument `event_level` to "second" to consider the last level of the factor the level of interest. For multiclass extensions involving one-vs-all comparisons (such as macro averaging), this option is ignored and the "one" level is always the relevant result.

Multiclass

roc_curve  

**Receiver operator curve**

**Description**

roc_curve() constructs the full ROC curve and returns a tibble. See roc_auc() for the area under the ROC curve.

**Usage**

roc_curve(data, ...)

## S3 method for class 'data.frame'
roc_curve(
  data,
  truth,
  ...,
  options = list(),
)
Arguments

- **data**: A data.frame containing the truth and estimate columns.
- **...**: A set of unquoted column names or one or more dplyr selector functions to choose which variables contain the class probabilities. If truth is binary, only 1 column should be selected. Otherwise, there should be as many columns as factor levels of truth.
- **truth**: The column identifier for the true class results (that is a factor). This should be an unquoted column name although this argument is passed by expression and supports quasiquotation (you can unquote column names). For _vec() functions, a factor vector.
- **options**: A list of named options to pass to pROC::roc() such as smooth. These options should not include response, predictor, levels, quiet, or direction.
- **na_rm**: A logical value indicating whether NA values should be stripped before the computation proceeds.
- **event_level**: A single string. Either "first" or "second" to specify which level of truth to consider as the "event". This argument is only applicable when estimator = "binary". The default uses an internal helper that generally defaults to "first", however, if the deprecated global option yardstick.event_first is set, that will be used instead with a warning.

Details

roc_curve() computes the sensitivity at every unique value of the probability column (in addition to infinity and minus infinity). If a smooth ROC curve was produced, the unique observed values of the specificity are used to create the curve points. In either case, this may not be efficient for large data sets.

There is a ggplot2::autoplot() method for quickly visualizing the curve. This works for binary and multiclass output, and also works with grouped data (i.e. from resamples). See the examples.

Value

A tibble with class roc_df or roc_grouped_df having columns specificity and sensitivity. If an ordinary (i.e. non-smoothed) curve is used, there is also a column for .threshold.

Multiclass

If a multiclass truth column is provided, a one-vs-all approach will be taken to calculate multiple curves, one per level. In this case, there will be an additional column, .level, identifying the "one" column in the one-vs-all calculation.
Relevant Level

There is no common convention on which factor level should automatically be considered the "event" or "positive" result when computing binary classification metrics. In yardstick, the default is to use the first level. To alter this, change the argument event_level to "second" to consider the last level of the factor the level of interest. For multiclass extensions involving one-vs-all comparisons (such as macro averaging), this option is ignored and the "one" level is always the relevant result.

Examples

```r
# Two class example

data(two_class_example)

roc_curve(two_class_example, truth, Class1)
```

# Visualize the curve using ggplot2 manually

```r
library(ggplot2)
library(dplyr)

roc_curve(two_class_example, truth, Class1) %>%
  ggplot(aes(x = 1 - specificity, y = sensitivity)) +
  geom_path() +
  geom_abline(lty = 3) +
  coord_equal() +
  theme_bw()
```

# Or use autoplot

```r
autoplot(roc_curve(two_class_example, truth, Class1))
```

## Not run:
# Multiclass one-vs-all approach
# One curve per level
hpc_cv %>%
  filter(Resample == "Fold01") %>%
  roc_curve(obs, VF:L) %>%
  autoplot()

# Same as above, but will all of the resamples
hpc_cv %>%
  group_by(Resample) %>%
  roc_curve(obs, VF:L) %>%
  autoplot()

## End(Not run)

**rpd**

*Ratio of performance to deviation*

**Description**

These functions are appropriate for cases where the model outcome is a numeric. The ratio of performance to deviation (rpd()) and the ratio of performance to inter-quartile (rpiq()) are both measures of consistency/correlation between observed and predicted values (and not of accuracy).

**Usage**

```r
rpd(data, ...)
```

### S3 method for class 'data.frame'

```r
rpd(data, truth, estimate, na_rm = TRUE, ...)
```

```r
rpd_vec(truth, estimate, na_rm = TRUE, ...)
```

**Arguments**

- **data**
  A `data.frame` containing the truth and estimate columns.

- **...**
  Not currently used.

- **truth**
  The column identifier for the true results (that is numeric). This should be an unquoted column name although this argument is passed by expression and supports *quasiquotation* (you can unquote column names). For `_vec()` functions, a numeric vector.

- **estimate**
  The column identifier for the predicted results (that is also numeric). As with truth this can be specified different ways but the primary method is to use an unquoted variable name. For `_vec()` functions, a numeric vector.

- **na_rm**
  A logical value indicating whether NA values should be stripped before the computation proceeds.
In the field of spectroscopy in particular, the ratio of performance to deviation (RPD) has been used as the standard way to report the quality of a model. It is the ratio between the standard deviation of a variable and the standard error of prediction of that variable by a given model. However, its systematic use has been criticized by several authors, since using the standard deviation to represent the spread of a variable can be misleading on skewed dataset. The ratio of performance to inter-quartile has been introduced by Bellon-Maurel et al. (2010) to address some of these issues, and generalise the RPD to non-normally distributed variables.

A tibble with columns .metric, .estimator, and .estimate and 1 row of values.
For grouped data frames, the number of rows returned will be the same as the number of groups.
For rpd_vec(), a single numeric value (or NA).

**rsq**

**R squared**

### Description

Calculate the coefficient of determination using correlation. For the traditional measure of R squared, see `rsq_trad()`.

### Usage

```r
rsq(data, ...)
```

```r
## S3 method for class 'data.frame'
rsq(data, truth, estimate, na_rm = TRUE, ...)
```

```r
rsq_vec(truth, estimate, na_rm = TRUE, ...)
```

### Arguments

- **data**: A `data.frame` containing the truth and estimate columns.
- **...**: Not currently used.
- **truth**: The column identifier for the true results (that is numeric). This should be an unquoted column name although this argument is passed by expression and supports quasiquotation (you can unquote column names). For _vec() functions, a numeric vector.
estimate The column identifier for the predicted results (that is also numeric). As with truth this can be specified different ways but the primary method is to use an unquoted variable name. For _vec() functions, a numeric vector.

na_rm A logical value indicating whether NA values should be stripped before the computation proceeds.

Details

The two estimates for the coefficient of determination, rsq() and rsq_trad(), differ by their formula. The former guarantees a value on (0, 1) while the latter can generate inaccurate values when the model is non-informative (see the examples). Both are measures of consistency/correlation and not of accuracy.

rsq() is simply the squared correlation between truth and estimate.

Because rsq() internally computes a correlation, if either truth or estimate are constant it can result in a divide by zero error. In these cases, a warning is thrown and NA is returned. This can occur when a model predicts a single value for all samples. For example, a regularized model that eliminates all predictors except for the intercept would do this. Another example would be a CART model that contains no splits.

Value

A tibble with columns .metric, .estimator, and .estimate and 1 row of values.
For grouped data frames, the number of rows returned will be the same as the number of groups.
For rsq_vec(), a single numeric value (or NA).

# a divide by zero error in the correlation calculation.
# 'NA' will be returned in these cases.
truth <- c(1, 2)
estimate <- c(1, 1)
rsq_vec(truth, estimate)

rsq_trad R squared - traditional

Description

Calculate the coefficient of determination using the traditional definition of R squared using sum of squares. For a measure of R squared that is strictly between (0, 1), see rsq().

Usage

rsq_trad(data, ...)

## S3 method for class 'data.frame'
rsq_trad(data, truth, estimate, na_rm = TRUE, ...)

rsq_trad_vec(truth, estimate, na_rm = TRUE, ...)
Arguments

data   A data.frame containing the truth and estimate columns.
...   Not currently used.
truth   The column identifier for the true results (that is numeric). This should be
        an unquoted column name although this argument is passed by expression and
        supports quasiquotation (you can unquote column names). For _vec() functions,
        a numeric vector.
estimate   The column identifier for the predicted results (that is also numeric). As with
            truth this can be specified different ways but the primary method is to use an
            unquoted variable name. For _vec() functions, a numeric vector.
na_rm   A logical value indicating whether NA values should be stripped before the
        computation proceeds.

Details

The two estimates for the coefficient of determination, rsq() and rsq_trad(), differ by their
formula. The former guarantees a value on (0, 1) while the latter can generate inaccurate values when
the model is non-informative (see the examples). Both are measures of consistency/correlation and

# sens

## Description

These functions calculate the sens() (sensitivity) of a measurement system compared to a reference result (the "truth" or gold standard). Highly related functions are spec(), ppv(), and npv().

## Usage

sens(data, ...)

## S3 method for class 'data.frame'
sens(
  data,
  truth,
  estimate,

estimator = NULL,
na_rm = TRUE,
event_level = yardstick_event_level(),
... 
)
sens_vec(
  truth,
estimate,
estimator = NULL,
na_rm = TRUE,
event_level = yardstick_event_level(),
... 
)
sensitivity(data, ...)

## S3 method for class 'data.frame'
sensitivity(
  data,
  truth,
estimate,
estimator = NULL,
na_rm = TRUE,
event_level = yardstick_event_level(),
... 
)
sensitivity_vec(
  truth,
estimate,
estimator = NULL,
na_rm = TRUE,
event_level = yardstick_event_level(),
... 
)

Arguments

- **data**
  - Either a `data.frame` containing the `truth` and `estimate` columns, or a `table/matrix` where the true class results should be in the columns of the table.
  - Not currently used.

- **truth**
  - The column identifier for the true class results (that is a `factor`). This should be an unquoted column name although this argument is passed by expression and supports quasiquotation (you can unquote column names). For `_vec()` functions, a `factor` vector.

- **estimate**
  - The column identifier for the predicted class results (that is also `factor`). As with `truth` this can be specified different ways but the primary method is to use
an unquoted variable name. For _vec() functions, a factor vector.

**estimator**

One of: "binary", "macro", "macro_weighted", or "micro" to specify the type of averaging to be done. "binary" is only relevant for the two class case. The other three are general methods for calculating multiclass metrics. The default will automatically choose "binary" or "macro" based on estimate.

**na_rm**

A logical value indicating whether NA values should be stripped before the computation proceeds.

**event_level**

A single string. Either "first" or "second" to specify which level of truth to consider as the "event". This argument is only applicable when estimator = "binary". The default uses an internal helper that generally defaults to "first", however, if the deprecated global option yardstick.event_first is set, that will be used instead with a warning.

**Details**

The sensitivity (sens()) is defined as the proportion of positive results out of the number of samples which were actually positive.

When the denominator of the calculation is 0, sensitivity is undefined. This happens when both # true_positive = 0 and # false_negative = 0 are true, which mean that there were no true events. When computing binary sensitivity, a NA value will be returned with a warning. When computing multiclass sensitivity, the individual NA values will be removed, and the computation will proceed, with a warning.

**Value**

A tibble with columns .metric, .estimator, and .estimate and 1 row of values.

For grouped data frames, the number of rows returned will be the same as the number of groups.

For sens_vec(), a single numeric value (or NA).

**Relevant Level**

There is no common convention on which factor level should automatically be considered the "event" or "positive" result when computing binary classification metrics. In yardstick, the default is to use the first level. To alter this, change the argument event_level to "second" to consider the last level of the factor the level of interest. For multiclass extensions involving one-vs-all comparisons (such as macro averaging), this option is ignored and the "one" level is always the relevant result.

**Multiclass**

Macro, micro, and macro-weighted averaging is available for this metric. The default is to select macro averaging if a truth factor with more than 2 levels is provided. Otherwise, a standard binary calculation is done. See vignette("multiclass","yardstick") for more information.

**Implementation**

Suppose a 2x2 table with notation:
The formulas used here are:

\[
\text{Sensitivity} = \frac{A}{A + C}
\]

\[
\text{Specificity} = \frac{D}{B + D}
\]

\[
\text{Prevalence} = \frac{A + C}{A + B + C + D}
\]

\[
\text{PPV} = \frac{\text{Sensitivity} \times \text{Prevalence}}{\text{Sensitivity} \times \text{Prevalence} + (1 - \text{Specificity}) \times (1 - \text{Prevalence})}
\]

\[
\text{NPV} = \frac{\text{Specificity} \times (1 - \text{Prevalence})}{(1 - \text{Sensitivity}) \times \text{Prevalence} + (\text{Specificity} \times (1 - \text{Prevalence}))}
\]

See the references for discussions of the statistics.

**smape**  
*Symmetric mean absolute percentage error*

**Description**

Calculate the symmetric mean absolute percentage error. This metric is in *relative units*.

**Usage**

```r
smape(data, ...)  
```

## S3 method for class 'data.frame'
`smape(data, truth, estimate, na_rm = TRUE, ...)`

```r
smape_vec(truth, estimate, na_rm = TRUE, ...)
```

**Arguments**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>data</td>
<td>A <code>data.frame</code> containing the truth and estimate columns.</td>
</tr>
<tr>
<td>...</td>
<td>Not currently used.</td>
</tr>
<tr>
<td>truth</td>
<td>The column identifier for the true results (that is numeric). This should be an unquoted column name although this argument is passed by expression and supports <em>quasiquotation</em> (you can unquote column names). For _vec() functions, a numeric vector.</td>
</tr>
<tr>
<td>estimate</td>
<td>The column identifier for the predicted results (that is also numeric). As with truth this can be specified different ways but the primary method is to use an unquoted variable name. For _vec() functions, a numeric vector.</td>
</tr>
<tr>
<td>na_rm</td>
<td>A logical value indicating whether NA values should be stripped before the computation proceeds.</td>
</tr>
</tbody>
</table>
Details

This implementation of `smape()` is the "usual definition" where the denominator is divided by two.

Value

A tibble with columns `.metric`, `.estimator`, and `.estimate` and 1 row of values.
For grouped data frames, the number of rows returned will be the same as the number of groups.
For `smape_vec()`, a single numeric value (or NA).

Examples

# Supply truth and predictions as bare column names
smape(solubility_test, solubility, prediction)

library(dplyr)

set.seed(1234)
size <- 100
times <- 10

# create 10 resamples
solubility_resampled <- bind_rows(
    replicate(
        n = times,
        expr = sample_n(solubility_test, size, replace = TRUE),
        simplify = FALSE
    ),
    .id = "resample"
)

# Compute the metric by group
metric_results <- solubility_resampled %>%
    group_by(resample) %>%
    smape(solubility, prediction)

metric_results

# Resampled mean estimate
metric_results %>%
    summarise(avg_estimate = mean(.estimate))
Solubility Predictions from MARS Model

Details
For the solubility data in Kuhn and Johnson (2013), these data are the test set results for the MARS model. The observed solubility (in column solubility) and the model results (prediction) are contained in the data.

Value
solubility_test
a data frame

Source

Examples
data(solubility_test)
str(solubility_test)

Specificity

Description
These functions calculate the spec() (specificity) of a measurement system compared to a reference result (the "truth" or gold standard). Highly related functions are sens(), ppv(), and npv().

Usage
spec(data, ...)

## S3 method for class 'data.frame'
spec(
data,
truth,
estimate,
estimator = NULL,
na_rm = TRUE,
event_level = yardstick_event_level(),
...
)

spec_vec(
  truth,
  estimate,
  estimator = NULL,
  na_rm = TRUE,
  event_level = yardstick_event_level(),
...
)

specificty(data, ...)

## S3 method for class 'data.frame'
specificity(
  data,
  truth,
  estimate,
  estimator = NULL,
  na_rm = TRUE,
  event_level = yardstick_event_level(),
...
)

specificity_vec(
  truth,
  estimate,
  estimator = NULL,
  na_rm = TRUE,
  event_level = yardstick_event_level(),
...
)

Arguments

data Either a data.frame containing the truth and estimate columns, or a table/matrix where the true class results should be in the columns of the table.

... Not currently used.

truth The column identifier for the true class results (that is a factor). This should be an unquoted column name although this argument is passed by expression and supports quasiquotation (you can unquote column names). For _vec() functions, a factor vector.

estimate The column identifier for the predicted class results (that is also factor). As with truth this can be specified different ways but the primary method is to use an unquoted variable name. For _vec() functions, a factor vector.
estimator

One of: "binary", "macro", "macro_weighted", or "micro" to specify the type of averaging to be done. "binary" is only relevant for the two class case. The other three are general methods for calculating multiclass metrics. The default will automatically choose "binary" or "macro" based on estimate.

na_rm

A logical value indicating whether NA values should be stripped before the computation proceeds.

event_level

A single string. Either "first" or "second" to specify which level of truth to consider as the "event". This argument is only applicable when estimator = "binary". The default uses an internal helper that generally defaults to "first", however, if the deprecated global option yardstick.event_first is set, that will be used instead with a warning.

Details

The specificity measures the proportion of negatives that are correctly identified as negatives.

When the denominator of the calculation is 0, specificity is undefined. This happens when both # true_negative = 0 and # false_positive = 0 are true, which mean that there were no true negatives. When computing binary specificity, a NA value will be returned with a warning. When computing multiclass specificity, the individual NA values will be removed, and the computation will proceed, with a warning.

Value

A tibble with columns .metric, .estimator, and .estimate and 1 row of values.

For grouped data frames, the number of rows returned will be the same as the number of groups.

For spec_vec(), a single numeric value (or NA).

Relevant Level

There is no common convention on which factor level should automatically be considered the "event" or "positive" result when computing binary classification metrics. In yardstick, the default is to use the first level. To alter this, change the argument event_level to "second" to consider the last level of the factor the level of interest. For multiclass extensions involving one-vs-all comparisons (such as macro averaging), this option is ignored and the "one" level is always the relevant result.

Multiclass

Macro, micro, and macro-weighted averaging is available for this metric. The default is to select macro averaging if a truth factor with more than 2 levels is provided. Otherwise, a standard binary calculation is done. See vignette("multiclass", "yardstick") for more information.

Implementation

Suppose a 2x2 table with notation:

<table>
<thead>
<tr>
<th>Reference</th>
<th>Predicted</th>
<th>Positive</th>
<th>Negative</th>
</tr>
</thead>
</table>

```
```
The formulas used here are:

\[
\text{Sensitivity} = \frac{A}{A + C}
\]

\[
\text{Specificity} = \frac{D}{B + D}
\]

\[
\text{Prevalence} = \frac{(A + C)}{(A + B + C + D)}
\]

\[
\text{PPV} = \frac{(\text{Sensitivity} \times \text{Prevalence})}{((\text{Sensitivity} \times \text{Prevalence}) + ((1 - \text{Specificity}) \times (1 - \text{Prevalence})))}
\]

\[
\text{NPV} = \frac{(\text{Specificity} \times (1 - \text{Prevalence}))}{(((1 - \text{Sensitivity}) \times \text{Prevalence}) + ((\text{Specificity} \times (1 - \text{Prevalence})))}
\]

See the references for discussions of the statistics.

**summary.conf_mat**  
*Summary Statistics for Confusion Matrices*

**Description**

Various statistical summaries of confusion matrices are produced and returned in a tibble. These include those shown in the help pages for `sens()`, `recall()`, and `accuracy()`, among others.

**Usage**

```r
## S3 method for class 'conf_mat'
summary(
  object,
  prevalence = NULL,
  beta = 1,
  estimator = NULL,
  event_level = yardstick_event_level(),
  ...
)
```

**Arguments**

- **object**  
  An object of class `conf_mat()`.

- **prevalence**  
  A number in (0, 1) for the prevalence (i.e. prior) of the event. If left to the default, the data are used to derive this value.

- **beta**  
  A numeric value used to weight precision and recall for `f_meas()`.

- **estimator**  
  One of: "binary", "macro", "macro_weighted", or "micro" to specify the type of averaging to be done. "binary" is only relevant for the two class case. The other three are general methods for calculating multiclass metrics. The default will automatically choose "binary" or "macro" based on estimate.
event_level  A single string. Either "first" or "second" to specify which level of truth to consider as the "event". This argument is only applicable when estimator = "binary". The default uses an internal helper that generally defaults to "first", however, if the deprecated global option yardstick.event_first is set, that will be used instead with a warning.

... Not currently used.

Value

A tibble containing various classification metrics.

Relevant Level

There is no common convention on which factor level should automatically be considered the "event" or "positive" result when computing binary classification metrics. In yardstick, the default is to use the first level. To alter this, change the argument event_level to "second" to consider the last level of the factor the level of interest. For multiclass extensions involving one-vs-all comparisons (such as macro averaging), this option is ignored and the "one" level is always the relevant result.

Two Class Predictions

Description

Two Class Predictions

Details

These data are a test set from a model built for two classes ("Class1" and "Class2"). There are columns for the true and predicted classes and column for the probabilities for each class.

Value

two_class_example

a data frame

Examples

data(two_class_example)
str(two_class_example)

# `truth` is a 2 level factor. The first level is `"Class1"`, which is the
# "event of interest" by default in yardstick. See the Relevant Level
# section in any classification function (such as `?pr_auc`) to see how
# to change this.
